A

Abstracts of War Surgery.....	92, Adv.
Accidents, Industrial, and Hygiene.....	581
Acidosis, Diagnosis of.....	87
Air Control and the Reduction of the Death Rate After Operation—Ellsworth Huntington.....	463
Air of Industrial Sections.....	692
Adams, Thomas—Housing Development as a Post-War Problem in Canada.....	344
Addison, Sir Christopher.....	462
Adenoids Handicap One Child in Ten.....	422
Advances in Public Health Administration.....	421
Advances in Pediatrics.....	728
Adventure of Life—Robert W. McKenna.....	458
Africa Completes Influenza Survey.....	150
Age and Occupational Disability.....	369
Aid, Medical, Free to Former Soldiers.....	56
Air Control: Next Great Step in Hospital Practice.....	537
Albaugh, R. P.—	
Anilin Poisoning.....	398
Benzol Poisoning.....	670
Brass Poisoning.....	202
Carbon Monoxide Poisoning.....	503
Lead Poisoning.....	137
Mercurial Poisoning.....	562
Wood Alcohol Poisoning.....	300
Albee, Fred H.—Rehabilitation of Disabled Workers and Industrial Cripples.....	215
Alcohol, Whole Truth About—George Elliott Flint.....	368, Adv.
America, What Is—Edward Alsworth Ross.....	649
American Hospital Conference Meets With Hospital Association.....	451
American Journal of Nursing.....	648
American Journal of Care for Cripples.....	31
American Public Health Association Elects Rankin President.....	712
American Pulley Company, Program of Health as Applied by the—William Alfred Sawyer.....	39
Andrews, B. Wylls—The International Medical Annual.....	548
Animal Parasites and Human Disease—Asa C. Chandler.....	650, Adv.
Anilin Poisoning—R. P. Albaugh.....	398
Anthrax.....	53
Antituberculosis Campaign in Oklahoma—Jules Schevitz.....	609
Antituberculosis Measures.....	84
Appeal for Human Embryological Material—William W. Graves.....	712
Arborization Block.....	265
Armour & Co., Health Supervision for Stockyards Workers.....	209
Armstrong, D. B.—A Consultation Service in Tuberculosis Work.....	633
Army, Dietary Studies in the.....	639
Army Physicians and Industrial Work.....	53
Athletes All—Walter Camp.....	368
Aspects, Medical and Surgical, of Aviation—H. Graeme Anderson.....	650, Adv.

B

Bacteriologists Meet in Boston.....	725
Bacteriology, Applied—C. H. Browning.....	458
Bacteriology and Mycology of Foods—Fred Wilbur Tanner.....	548
Baldwin, Bird T.—Occupational Therapy Applied to Restoration of Function of Disabled Joints.....	740
Bamberger, Arrie—Infections, Acute Septic, of the Fingers.....	43
Bardeen, C. R.—Medical Supervision of Students at Wisconsin.....	468
Barjon, F.—Radio-Diagnosis of Pleuro-Pulmonary Affections.....	184, Adv.
Bendixen, P. A.—Infections of the Upper Extremities.....	679
Benefits, Medical, and the Medical Profession Under Workmen's Compensation Laws—Carl Hookstadt.....	399
Benefits, Medical, Under Workmen's Compensation.....	597

MODERN MEDICINE

A Monthly Magazine of Medical & Health Progress for Physicians
& for Others Interested in Administrative, Industrial
& Social Health Problems

Editors ALEXANDER LAMBERT, M. D., S. S. GOLDWATER, M. D., and JOHN A. LAPP, LL.D.

Managing Editor JOHN A. LAPP

Editorial and Business Offices, 58 EAST WASHINGTON STREET, Chicago

Volume I.

MAY, 1919

Number 1

NOTES AND COMMENT

THE PURPOSE OF MODERN MEDICINE

MODERN MEDICINE makes its first appearance with this issue. The magazine is not merely "one more medical journal." It is rather a pioneer in a new era of medicine; and, while it breaks in no way with the splendid traditions of the profession, its concern is primarily along the lines of thought which will characterize leadership among physicians and surgeons in the new age now upon us.

The new age in medicine—what is it? The answer is that we must think of medicine today as including everything that will make people fit for service. To be fit for service is to be fit to do our individual part; to be fit as a factor physically, mentally, and spiritually in a great nation's progress. It means to be fit for life. In all the history of the world no such tremendous responsibility was ever before put upon a profession. Are the doctors prepared? Do they hear the call? Are they ready for action?

Let us look a little further. The war made a nation of us. We are an idealistic nation. The whole world trusts our idealism. We are happy, proud of ourselves, and prosperous. Almost overnight we have learned that happiness and prosperity live together; that to be well is the basis of happiness and prosperity; and that, somehow, all have a right to be well, just as soldiers and sailors in military service not only have a right to be well, but *must* be well in so far as the whole science of medicine, including sanitation, can keep them. Henceforward the practice of medicine in civil life must reckon with this conception.

One outcome of the situation is certain. Either the doctors will meet the new demand with ade-

quate intelligence and force, or changes will be brought about through swift, ill-advised, and perhaps prejudiced legislation. In the former case the profession will rise to even a more honored stratum of society; in the latter case—but let us not talk about that. MODERN MEDICINE believes that the doctors will rise to the need; that they have the wisdom and initiative to meet their inescapable responsibilities. MODERN MEDICINE is the clearing house for progress of this sort. Its field is not only the narrow confines of the art and science of medicine, but it has to do also with the application to public welfare of the whole knowledge of medicine and of sanitation. MODERN MEDICINE asks the constructive cooperation of the profession in order that its pages be pages of leadership, pages of *finding out* and *learning how* among world problems, which are medical problems, in these rudderless times.

The age in which we live is generous, but it also makes great demands. Industries of every description want their workers happy and productive. Fathers and mothers want the health of their children protected, in school, at play, and at home. They want their own health safeguarded. Municipalities and states are awakening to new conceptions along these lines. Laws are being proposed and enacted. And yet, for the very reason that physicians are devoted to the welfare of their patients, they are not keeping pace with these new demands. They are out of the main social currents, caring for the sick. All honor to men giving such service; but, looking forward, there is big work to do. To help in a worthy fashion is the primary intent in the minds of the editors.

THE RETURNING SOLDIERS

FOUR million men will soon have been returned to their homes after service in the army and navy. These men have been for months or years living a thoroughly organized group life. They have eaten and slept regularly; taken exercise and done work consistently; been cared for systematically; had medical oversight in sickness and in health; and have been scientifically clothed, shod, fed, and trained.

What does their return mean to their physical well being? Each one might well ask himself the question whether the standards of healthful living set for him in the army may be sustained in private life. The community might well ask the question whether those standards may not be at least approximated in the daily life of the people at all times, and particularly at this time when 4,000,000 potential missionaries of health are scattering to the four corners of the country.

That there will be a reaction from the regularity of military discipline need not be doubted. Men who have risen at the reveille and retired at taps for some months will welcome the release, and they will tend to revert to the irregularity of their former life. Likewise, men who have had a set diet will revel in the free choice of food and drink as a sport of freedom. They can, however, scarcely forget the joy of vigorous life and that regularity was the basis of their vigor. It would be a strange evidence of human perversity if the lessons of balanced and regular diet, recreative work and sleep were forgotten by the majority of the men.

It is reasonably certain that in some directions the experience of the war will be preserved. Comfortable clothes and shoes, determined by expert advice, will hardly be exchanged for the dictates of mere fashion and the whim of manufacturers. Shoes will be made to fit the feet and will not be a mold to shape the feet. Clothes designed for health and warmth will be better understood by hundreds of thousands.

In another direction the impress of the army life cannot be effaced. The men have grown accustomed to preventive medicine. Physicians have been on the job to keep men well rather than to cure them when sick. To many this was the first experience with the physician's work in the rôle of prevention. They could not help but see the advantage of applying the ounce of prevention. They cannot afford to forget.

Then there is the care of the teeth, and the work of the army and navy dentists. Defective teeth constituted one of the principal causes of rejection in the draft. Defective teeth were also often the sources of origin of other defects. Men

have now discovered the importance of good teeth to health and the lesson will not be lost.

The Government has adopted the wise policy of retaining men in the service or in the hospitals until they are physically cured so far as is possible. There will be no spread of contagion such as followed demobilization in other wars. The value of health is being impressed in a variety of ways, chief of which is the importance which the army and navy attach to physical fitness as a requirement for discharge. The belief in physical preparedness pervaded to a considerable extent the whole population and it may be confidently expected that in the main the results will be good, although we shall probably see many examples of individual deterioration as a result of the reaction from a disciplined routine of life.

PREPAREDNESS AGAINST INFLUENZA

THE epidemic of influenza which has just run its course and even yet lurks among us in its milder forms has exacted a fearful toll in life and health. On account of the faulty reports as to the cause of death we shall probably never know the exact number of fatalities for which it has been directly responsible.

Warned for some months in advance of its approach, we were quite unprepared when it broke upon us in all its fury. Our hospital and nursing facilities were at once taxed beyond capacity, and methods of prophylaxis were, as a general rule, organized only after the disease reached a community and not before. Our research laboratories for the most part got under way their investigations after the epidemic had well nigh run its course. Even the technic of culturing the influenza bacillus had to be learned anew and the difficulties mastered. When at last the workers had become oriented and had their plans made for investigations along new lines and with more modern methods, the opportunity was gone—the epidemic had passed. The clinicians were equally unprepared. An appreciation of the fatality of the pneumonia, the diagnostic significance of the abundant fine crackling râle, the futility of the usual drug therapy, including that of the coal tar products, all had to be relearned.

It might be argued that the epidemic came upon us at a most unfortunate time; that the ranks of our civilian physicians were much depleted; that our laboratory organizations were sadly disrupted. Far outweighing these disadvantages, it would seem, is the fact that several million of our men were gathered together in orderly arrangement, under discipline, and with facilities for medical observations of a systematic

kind distinctly superior on the average to anything on the same scale in civil life. No, we should not seek for extenuating circumstances; we should face the facts. We were entirely unprepared. The disease, though it has swept over the world many times in similar epidemics during the past few centuries, was to our generation of physicians something entirely new. We were astonished, overwhelmed.

Shall the lesson pass unheeded? All the history of the past teaches us that another epidemic is to come in perhaps twenty or forty, or who knows how many years. The toll in life, if our population increases in the expected ratio, may be little short of a million. Would it not be wise to prepare to meet the problem now? Is it not possible to establish by endowment or otherwise one or several well equipped centers for the study of the disease? Here could be gathered all available information on the subject; methods of combating the infection could be studied and elaborated. Investigations into the etiology could be kept under way—if indeed such a thing is possible when the disease is not epidemic—and if this is not possible every means toward the fullest utilization of the next epidemic for intensive study could be kept constantly mobilized.

We have in the past spent huge sums in preparation for the eventuality of war; we have at much cost constructed arms and armament of all sort which have become obsolete without seeing use; men have been trained and grown old in service without seeing battle. We have before us the glorious hope of no more war and of no more need of preparedness for war. Can we not turn some part of the gigantic effort which we have been wont to expend in the cause of war into new channels? Can we not prepare for the problems of peace even though those problems may not arise again during our own lifetime?

HEALTH AND NATIONAL EFFICIENCY

THE health of a people determines their power as a nation. There is no other asset so important in national well-being as physical strength, equal to the contests of peace and war. The individual cannot succeed without physical power; industry will fail in the competition of the world without it; and nations will remain backward or will be destroyed by its insufficiency.

"The most valuable resource of any country," says Prof. Thomas Nixon Carver, "is its fund of human energy, that is, the working power, both mental and physical, of its people. It is safe to say that any capable race of men who will conserve, economize and utilize that fund

will be able not only to extract a living but actually to prosper in the midst of poor natural surroundings. On the other hand, if they fail to economize their fund of energy, if they waste and dissipate it, they will certainly decay in the midst of the richest geographical and material resources."

To meet this vital national need for health we have depended largely upon the individual himself. Each man has been expected to provide for his own medical care on an individualistic basis. The physician sold his services to the individual. The public merely gave meager protection against contagious diseases and supplied medical charity to the dependent. Disease among the independent, self-supporting people has been largely an individual matter between the man and his physician. Adequate service for the prevention as well as the cure of disease has not been possible under such conditions. The answer to the problem on the part of physicians is being made through organized, or group practice, and on the part of the public by providing hospitals, dispensaries, and clinics and the development of public health work.

Attention to the tendencies in public health work and in medical practice will make the new developments clear. Public health work began as a police protection against the spread of contagious diseases. It continued to be that for a long time and, even at present, the principal motive is the same in the greater part of the country. The weapons which were used were the pest house and the quarantine. We still protect against contagion, but we go farther back to prevent original causes. We also go forward into the field to prevent disease of all kind; to educate the people in health practice; to train physicians, nurses and sanitarians as well as to treat the sick. The hospitals, dispensaries, clinics, public health nurses, medical supervisors of schools, industrial physicians, laboratories, and free medicines, have brought health service into the realm of medical practice. At the same time medical practice has become more and more preventive in character. More physicians than formerly are engaged in keeping the people well. The physician is coming to treat the man rather than the disease; and to treat the man requires that the physician go behind the immediate disease to look for the ultimate causes in the life and environment of his patient. In the broadened stream of medical science, the physician has found the necessity for specialization, and the specialists have found the necessity for coordinating their specialties into a unitary practice through group diagnosis and treatment.

However we look at the matter, whether from

the standpoint of the individual, the physician, or the public, we find that the tendency is toward the prevention and treatment of disease as a vast social service. The ultimate end is social health and national welfare.

That we have occasion to be disturbed about present conditions will be clearly shown in the statement of the problem of sickness:

The loss from sickness and disability among the people of this country is enormous. All the evidence goes to show that every worker loses about 9 days on the average every year. Thirty million workers lose, therefore, 270,000,000 days in a year, which amounts to \$540,000,000 at \$2.00 a day. The cost of medical care at present amounts to an average of about \$30.00 to \$35.00 per family every year. The 25,000,000 families in the country spend, therefore, \$750,000,000 to \$875,000,000 for medical service, mostly curative. To this should be added \$150,000,000 expended for patent medicine. The public spends \$70,000,000 for state institutions for the care of the insane, epileptic, feeble-minded and other defectives, and untold amounts for free service by hospitals, dispensaries and physicians. Fully 35 per cent of all the enormous amounts expended in charitable relief, public and private, is due to sickness, while an equal amount of old age dependency is due to the same cause. The total cost in dollars and cents is simply astounding.

The amount of money invested in all kinds of equipment for the care of the sick would float a good sized Liberty Loan. The investment includes asylums, hospitals, dispensaries, practitioners' offices, medical and dental schools, supply factories, laboratories and public health equipment. It is obvious that the problem is one of great economic importance, to say nothing of the human aspects of pain and suffering.

It is proper to raise the question and discuss it in season and out, whether the vast service of medical care and health protection required by a problem of these proportions is organized efficiently to promote health and prevent disease, and whether the existing medical knowledge and skill in the country are made to function fully for the high aims of national efficiency.

DISEASE AND WOUNDS IN THE WAR

SCIENCE made the world war deadlier than any previous war, but medical skill restored the balance. The instruments of war were more destructive than ever, but medical science was more reconstructive than ever. More men were killed outright, but fewer died from infections and neglected wounds, and fewer from the rav-

ages of disease in proportion to numbers. Foresight and sanitation prevented contagion.

The compiled figures on pensions by the English Ministry of Pensions throw much light on the relative distribution of disease and wounds in the great war. While this war has been a triumph for the physician in the conquest of disease in the army, yet a majority of the pensions granted down to September 1, 1918, were granted on account of disease.

Out of a total of 421,877 pensions granted, tuberculosis and chest complaints were responsible for 47,078 or 11.2 per cent; rheumatism for 27,424, or 6.5 per cent; heart disease 41,699 or 9.9 per cent; nervous diseases 25,165 or 6 per cent; epilepsy 4,257 or 1 per cent; miscellaneous diseases, including Bright's disease, debility, ulcer of the stomach, varicocele, enteric and malarial, spinal, appendiceal, amounted to 81,381 or 19.3 per cent.

Altogether the number of persons pensioned on account of wounds was 42 per cent of the total as against 58 per cent on account of disease.

The data of American experience is still meager, but reports from the Federal Board for Vocational Education indicate that of the 7,710 cases dealt with up to Jan. 31, 1919, by far the larger portion was due to disease. Tuberculosis was responsible for 2,791 cases or 36.2 per cent; heart disease for 843 cases or 10.9 per cent; nervous diseases and shell shock 294 cases or 3.9 per cent; insanity 318 cases, or 4 per cent; other diseases 2,291 or 29.7 per cent. The total number of cases on account of wounds was 915 or 12 per cent.

The short duration of American participation in the actual fighting, and the large number of men in camps make it probable that disease will, by far, exceed wounds as causes of disability.

The contrast with previous wars is striking. Our Civil War produced 309,790 casualties from wounds and disease, of which 110,070 were on account of wounds and 199,720 on account of disease. Epidemics persisted and caused a heavy drain upon the man-power of both armies.

Figures are not available to show the disabilities other than death respectively by disease and battle wounds, but all the evidence indicates that disease was the most powerful factor in creating disabilities. This was decidedly true of the Spanish-American War, in which large numbers were permanently broken in health. Diseases which wrecked the lives of thousands in 1898 were entirely conquered in the armies of the fighting nations in the world war.

We trust that the achievements of medicine in the war will be completely and popularly set forth in the near future for the stimulus it will give to preventive medicine.

THE CARE OF THE SICK IN THE UNITED STATES IN 1919

BY S. S. GOLDWATER, M.D., DIRECTOR, MOUNT SINAI HOSPITAL, NEW YORK, FORMER CONSULTANT ON HEALTH AND HOSPITALS TO THE BOARD OF ESTIMATE AND APPORTIONMENT OF THE CITY OF NEW YORK

FRENCH Government observers, impressed by the work done by various American medical agencies in France during the war, have recently been sent to this country for the purpose of studying our methods and institutions for the care of the sick. In view of the immense number of factors involved, one wonders to what extent these foreign visitors have been able, in the course of their brief inquiries, to form any adequate idea of the manner in which our sick are really cared for in and out of institutions.

Any serious study of the problem of the care of the sick must necessarily begin with their enumeration and classification, a task which, so far as is known, no agency, public or private, has ever had the hardihood or the opportunity to undertake on a nation-wide scale. What such a complete enumeration and classification would reveal may be inferred from statistics that have been compiled in the course of local investigations.

The Extent of Sickness

Inquiries into the prevalence of disease may concern themselves first, with sickness of a grade which impairs industrial and social efficiency, and second, with sickness of a lighter grade, which does not appreciably or immediately affect the ability of the individual to carry on his work or to maintain his normal social relations and activities. The extent of sickness of the latter grade is ascertained only with difficulty.

Throwing light upon the prevalence of sickness of a more serious character, there are the official reports of notifiable communicable and preventable disease, and, apart from such reports, sickness censuses of whole populations or of population groups. Among the records available are those of fraternal societies, health and accident insurance organizations, industrial and other benefit funds, and a few scattered community sickness censuses, notably those conducted in Boston, Trenton, Rochester, and elsewhere, under

the auspices of the Metropolitan Life Insurance Company; in certain Manhattan districts by the health department in the city of New York; the Dutchess County survey directed by the New York State Charities Aid Association; and the South Framingham community studies.

Statistics from both foreign and domestic sources indicate that in a modern industrial population there is an average of from six to ten

days of acute illness for each worker. Other studies have shown that in American communities that are liberally provided with hospitals, there are at any given time approximately ten persons acutely sick for each person undergoing hospital treatment. On a basis of ten days' acute illness per person per annum, New York City, with its population of approximately 5,500,000, would have about 150,000 sick daily. In the general hospitals of New York City (leaving out of the calculation hospitals for the insane and institutions caring for chronic cases) there are under treatment in normal times about 15,000 patients or one in ten of the city's 150,000 sick.

In a survey in a tenement district conducted by the New York City Department of Health in February, 1914, a sickness rate of 2.4 per cent was established, which, applied to the city as a whole, would represent approximately 130,000 current serious cases. The health department's studies show that the cases of sickness included in the district census just referred to were distributed as to treatment in the following manner:

Receiving treatment in dispensaries.....	35%
Receiving treatment in hospitals.....	10%
Treatment by private physicians.....	34%
Self-treatment and not treated.....	21%

So far as hospital and dispensary activities are concerned, the figures established in this local survey by the department of health are probably fairly representative of the conditions in the city of New York as a whole. In this study it was found that approximately 35 per cent of all of the

incapacitated sick were undergoing dispensary treatment. If the same sickness rate and the same rate of dispensary attendance rate held for the entire city, there would be 127,000 sick in the city, of whom about 45,000 would be registered at dispensaries. The actual or recorded dispensary attendance in New York City is about 15,000 per dispensary day (Sundays and holidays are excluded from this calculation) and, inasmuch as it has been shown that each registered dispensary patient attends approximately three times, there are in the dispensaries of New York City at any given time approximately 45,000 registered cases. In Boston, with a population equal to about one-seventh of the population of New York, dispensary attendance is about 3,500 for each day in the year, excluding Sundays and holidays.

Neglected Sickness

The extent to which serious sickness is neglected is just beginning to be appreciated. Various community studies show from 21 to 40 per cent of uncared-for illness (the actual figures obtained by investigation in New York are 21 per cent, for Dutchess County 26 per cent, Boston 28 per cent, Rochester 40 per cent). Physical examinations in the public schools and among adult groups reveal a wide prevalence of morbid conditions which call for attention, but of which no cognizance is taken in ordinary sickness surveys, which deal only with obvious, declared, or admitted illness. In a "medical examination drive" in South Framingham, which had for its object the disclosure of unrecognized cases of illness as well as the enumeration and classification of known cases, 3,456 out of 4,489 persons examined, or 77 per cent, showed some physical disorder or defect requiring medical attention. In a previous sickness census among the same group the number of sick declarants was only one-twelfth of the number found in the course of the medical examination drive to be in actual need of medical attention. The significance of these figures might not have been understood by the general public two years ago, but, since the beginning of the war, the people have been greatly enlightened by the widely advertised findings of draft boards and army doctors in the examination of military registrants and recruits.

With the gradual extension of the system of periodic physical examinations now carried on by various organizations in industrial and mercantile establishments, among groups of civil employees, among pupil nurses and other hospital workers, among children attending public school, and even among infants, a vast amount of information is being accumulated relating to phys-

ical defects and mild forms of disease, and this rapidly accumulating fund of facts will be of enormous benefit to the people when it has been properly digested and its lessons have been intelligently applied by legislatures, public health administrators, industrial managers, hospital boards, schools of medicine and of nursing, private physicians, welfare organizations, and the public.

Not far removed from the sheer neglect of sickness is self-diagnosis and self-treatment, practiced chiefly at the behest and under the dubious guidance of the makers and vendors of patent and proprietary medicines. It would be rash to assume that this traffic can be completely destroyed or eradicated. Misrepresentation of the character of secret remedies is far less flagrant than was the case ten years ago. For the progress that has been made credit is due to the educational activities of the United States Public Health Service and of state and local departments of health, to Congress for the passage of a law which makes demonstrable misrepresentation of the therapeutic effects of a nostrum a criminal act, to the Bureau of Chemistry of the Department of Agriculture for the active and unremitting prosecution of violators of this law, to the enlightened government of the Philippine Islands for banishing secret nostrums altogether, and to the New York City Department of Health for offering vendors in New York City the option of frank and honest labeling or, in lieu thereof, the registration of secret formulas with the department. It is true that the New York ordinance has been declared unconstitutional by the State Court of Appeals, but in rendering its decision the court very significantly expressed the opinion that the enactment of an ordinance of the general character of the one in question was entirely within the "police power" which the health department exercises, and pointed out how, by a slight amendment, the Court's objection to the present ordinance, which was purely technical, could be overcome.

The Private Practitioner

Turning from the neglected to the attended sick, the observer may well be appalled by the difficulty of the task of making a comprehensive survey of so wide and varied a field. The present article will attempt nothing but a rough enumeration of the instrumentalities concerned in the care of the sick both in and apart from institutions. Here and there a word may be admitted concerning the influences by which such instrumentalities are moulded and their effectiveness determined.

Obviously, the most important agency in the care of the sick apart from institutions is the private practitioner. In the New York census, to which reference has already been made, it was found that of the total number of sick declarants in the district under investigation, 45 per cent were being treated in hospitals or at dispensaries, leaving 55 per cent under domiciliary or private treatment. Of those at home some were neglected cases, but approximately two-thirds were undergoing treatment by private physicians. In localities in which hospital and dispensary facilities are less plentiful than in New York, a much larger proportion of the known sick are dependent for their care upon private physicians.

The geographic distribution of physicians shows marked variations. In some states, we find almost one physician to the square mile; in others, more sparsely settled, there is one physician to five hundred square miles. In the whole United States, there is said to be one practicing physician to about seven hundred persons. The ratio of physicians is now diminishing, for the number removed from practice annually by superannuation, death, change of occupation, and other causes is over five thousand, while the annual number of medical graduates is now only about three thousand.

For statistical purposes it may suffice to say that a certain percentage of the sick are attended by private physicians. The thoughtful investigator may be tempted to go a step further and inquire into the character of the treatment given; if he wishes to be thorough in his investigation, he will have to go still further and consider the education of the private practitioner. The content and method of medical education have undergone very decided improvement within the memory of man, and so far as regularly educated physicians are concerned, it might be unfair to quote the saying of Hippocrates that "physicians are many in title but few in reality." But with many states continuing to recognize such freakish cults as osteopathy, chiropractic, and naturopathy as legitimate forms of medical practice, one is tempted even now to take one's stand with Hippocrates. Even Christian Science probably has as many adherents today as in the time of Mrs. Eddy. The homeopaths, happily for everybody concerned, are gradually abandoning dogma and are aligning themselves with open-minded physicians who seek constantly to broaden and strengthen the scientific foundations of medical practice. Within the past few months one of the leading homeopathic schools has broken away from its old moorings.

Lodge and Benefit Fund Practice

Medical efficiency is determined by methods of practice as well as by preliminary medical education. The old relationship between a single patient and a single doctor is rapidly giving way to a new relationship, referred to under the term "group practice." There are two kinds of grouping in medical practice today. There may be a grouping of patients in the form of an association or society whose members share the medical services of a physician, or there may be a grouping or combination of doctors representing various branches of medicine, who offer to a single patient the benefits of their combined talent and training.

In lodges or medical benefit associations, one may observe in America (on a voluntary basis, however) some of the elements of that form of compulsory sickness or health insurance which is now a characteristic feature of the social organization of many of the civilized countries of the world, but not yet of the United States. In 1914, there were located in New York City thirty-six trade unions, mutual assessment, stock company, or fraternal society funds, carrying voluntary health insurance. Many of these organizations maintain headquarters in New York City and have branches throughout the country. In New York City alone these thirty-six organizations claimed 170,000 members. Twelve fraternal societies, included in this group, provided medical care; on the other hand, out of eleven trade union funds, only one offered medical care to its members.

State Care

In this country provision by the state for the care of the people in sickness has been almost wholly confined to the establishment of free hospitals and dispensaries, while the domiciliary care of the sick by the state has been limited to the care of the destitute. That a change in this respect is impending is the belief of many. The American Medical Association, in defining standards to which compulsory health insurance should conform in order to do justice to physician and patient, and in appointing a standing committee on social insurance, has virtually conceded that the issue is a practical one in this country. Eight states have appointed official commissions to report on the subject of health insurance, and organized labor, at first hostile, is now advocating in New York state and elsewhere a health insurance bill which, in addition to cash benefits, provides for medical and surgical treatment and nursing attendance for the insured employee and his family, dental care for the insured, and

maternity benefit for working mothers and for the wives of insured men. Employees are to be insured without physical examination, and there is to be free choice of physician.

Industrial Accidents

The care of injured industrial workers under workmen's compensation laws is a subject which might well be treated at length, but which in the present introductory article can only be referred to in passing. The first compensation or industrial accident insurance law to be enacted in the United States was the Maryland law of 1902. In 1910 the movement began to spread rapidly, and by 1913 thirty states had passed compensation laws. At present such legislation exists in thirty-eight states. In many of the states the insurance is optional and private; the first straight compulsory state insurance under a compulsory compensation law was enacted by the state of Washington in 1911. Our interest here is chiefly in the medical or rather the surgical service for which these laws provide. Among the medical profession there is considerable dissatisfaction with the rates that have been arbitrarily fixed as compensation for surgical service, and with the hostile attitude of stock companies which are permitted to carry "compensation" insurance. Unfair treatment has been charged to both sides. The companies are slowly learning that the cheapest treatment is not always the best.

Nursing Care

The physician has been spoken of as the essential factor in the treatment of the sick apart from institutions. A secondary factor of considerable importance is the nurse, who may be the full-fledged graduate of a school supervised by the state, and who may be registered with and, by inference, professionally vouched for by the state educational authorities, or who may be an unregistered nurse, systematically or unsystematically trained, or without any training at all. Registered nursing schools have graduated up to date in the United States nearly one hundred thousand women, of whom about half may still be engaged in nursing practice, the remainder having been lost to the profession through marriage, change of occupation, superannuation, disease, and death. Of new graduates there are perhaps twelve thousand annually. Accurate reports of the number of unregistered nurses are lacking. Nurses are registered by state boards in forty-five states and the District of Columbia; the three states that have no established system of state registration are Arizona, Nevada, and New Mexico.

In the procurement of nurses for duty in patients' homes, registries, commercial and non-commercial, play an important role. Commercial registries are commonly licensed under laws or ordinances which apply to employment agencies of all kinds. A considerable part of the public is at the mercy of commercial registries, and the stricter regulation of such registries has been urged.

Attendants, who occupy a position below the professional nurse in rank, are likewise in the field in large numbers; the legal standardization of the training of attendants is a subject which is at the present moment receiving attention in a number of states.

A bill at present before the Illinois legislature proposes to overcome the present shortage of nurses by establishing an eighteen months' course of training for women, who are to be called "Junior Nurses." A standard curriculum for schools of nursing proper has been proposed by the League for Nursing Education and is widely followed.

In order to provide domiciliary nursing service for the poor, district nursing organizations have been founded and are being generously supported. There are places in which the work of such organizations compares in volume and importance with the work of the local health departments.

Maternity work in the home is shared almost equally in the larger cities by midwives and physicians. In many localities midwives are subjected to little or no supervision or control. In New York, city and state, and in a few other states, health departments have concerned themselves with the education of the midwife and with the supervision of their work in the field. Certain foreign elements in the population show a strong preference for the midwife as against the physician. In teaching centers midwifery is practised by undergraduate medical students working under the supervision of instructors.

Public Health Agencies

In our rapid survey of the care of the sick, we must not lose sight of various public health activities, including the compulsory notification of contagious diseases, the object of which is the quarantining of such cases in their homes or in hospitals. Health department nurses are engaged in home nursing especially in connection with communicable disease, maternity and prenatal work, and the diseases of infancy. Health departments provide diagnostic clinics which often specialize in venereal and occupational diseases and in tuberculosis. The diagnostic laboratories of departments of health constitute an indispensable

aid to private physicians and render a most valuable service to the sick. Public health authorities, furthermore, supply antitoxins and vaccines, and may be credited with millions of successful preventive inoculations against smallpox and typhoid, diphtheria, and possibly poliomyelitis and influenza. The medical inspection of school children is a factor of the first importance in the detection of physical defects and in the early recognition of contagious diseases of childhood. In certain localities school clinics have been established, chiefly for the treatment of diseases of the eye, nose, throat, teeth, and skin. Last but not least among public health institutions is the babies' welfare station; the number of these stations is increasing daily.

In the treatment of injuries and of sudden emergencies the ambulance service comes into play. Various types of ambulance organizations may be found in this country. One form is the service connected with public or private hospitals; another form is that which is under police control. When, in catastrophes, the local medical and hospital service breaks down or fails to measure up to the need, the Civilian Relief Division of the American Red Cross comes into play, together with innumerable first aid societies of a local character.

Dispensaries

The institutional care of the sick includes care in dispensaries and in hospitals. The subject of dispensaries has recently been admirably reviewed by Davis and Warner in their book entitled "Dispensaries, Their Management and Development." Following these writers, we may classify dispensaries as to their medical scope, their relation to other medical institutions, or their public function. In their medical scope, dispensaries are either general, treating all diseases, or special, confined to one or a few specialties; in relation to other medical institutions, dispensaries may be classified as the out-patient departments of hospitals, and as out-patient institutions separate from hospitals; also as teaching and non-teaching, the former making systematic provision for the teaching of medical students, the latter assuming no such function. In their public aspects, some dispensaries are found which devote themselves entirely to clinical medicine, while others lay stress upon prophylaxis. Treatment and prophylaxis are both emphasized in the work of special dispensaries for tuberculosis and venereal diseases. Dental clinics are found in connection with dental colleges, general dispensaries, orthopedic dispensaries, and school clinics. Boston has a huge dental infirmary planned

for the dental treatment of the city's entire school population.

Lack of space forbids a complete analysis or even classification of dispensaries in the present article, but some idea of the extent and importance of the field may be formed when it is stated that in New York City alone, there are twenty-five different kinds of dispensaries to which about a million different persons resort annually for treatment. The number of visits paid by these patients in 1915 was 3,468,190. Dispensary attendance in New York City has been somewhat diminished during the war. One million fourteen thousand patients admitted for treatment in 1915 were arranged as follows:

Medical	21.7%
Surgical	18.5%
Pediatric	4.7%
Gynecologic	7.8%
Genito-urinary and skin.....	9.8%
Neurologic	2.3%
Eye, Ear, Nose and Throat.....	30.0%
Orthopedic	2.8%
Dental	2.4%

There are said to be in the United States today nine hundred general dispensaries and out-patient departments attached to general hospitals, one hundred special dispensaries and out-patient departments, and twelve hundred public health dispensaries.

The public supervision and regulation of dispensaries varies greatly. In certain parts of the country the very existence of dispensaries is ignored by the public authorities, while in other sections laws and ordinances have been most carefully compiled, with a view to the establishment of dispensaries, the protection of dispensaries from abuse, and in some instances, to the protection of dispensary patients from abuses which readily spring up in the absence of high ideals and legal standards. In New York, a dispensary may be established only with the approval of the state board of charities. In Massachusetts, a person or association desiring to conduct a dispensary must apply in writing to the state department of health.

Most dispensaries charge nominal fees; in some the service is wholly gratuitous, and recently "pay clinics," which charge fees that are moderate but sufficient to defray the bare cost of maintenance, including very moderate fees or salaries to the physicians in attendance, have been created in Boston, New York, and elsewhere.

Contributions in aid of dispensaries which are not self-supporting come from the same public and private sources upon which hospitals depend; these sources are classified in the section relating to hospitals.

Dispensaries have been severely and justly criticized for the indifferent character of their equipment and work, but notable improvement in this respect has taken place within the past few years. Standards of equipment, space, and time, and approved methods of organization have been proposed by the Associated Out-Patient Clinics of New York and by individual reformers, with good results. In the past physicians not only were expected to give their services to dispensaries gratuitously, but were asked to work under improper, almost impossible conditions. The better service which they and their patients are receiving today is reflected in the cost of dispensary operation, which in many instances has more than doubled in eight or ten years.

Hospitals

We come now to hospitals which may be classified as (a) public or (b) voluntary or private; or as (a) acute, (b) convalescent, or (c) chronic. The distinction between private and public hospitals is not always perfectly clear because many privately managed hospitals are supported in part by public funds. This is hardly the proper place to argue for or against state or municipal subsidies, but the question of the manner in which such subsidies should be granted is suggested as a subject worthy of the careful thought of the public health administrator and the social student. In Pennsylvania and some other states appropriations have been made without much system, and abuses have sprung up which it has been possible to avoid where appropriations have been carefully restricted and regulated.

The public hospitals in the United States fall into three groups of (a) Federal, (b) state, and (c) municipal and county. Among the medical institutions maintained by the Federal Government are military hospitals in great variety, (these are described in recent reports and bulletins issued from the Surgeon General's office) naval hospitals, and (under the jurisdiction of the United States Public Health Service) hospitals for the merchant marine, quarantine stations, the United States Hygienic Laboratory, and the recently authorized national leprosarium. The Public Health Service is concerned jointly with the health departments of states in the establishment and support of clinics for venereal diseases.

During the war the medical corps of the army was expanded from 500 men to nearly 40,000, and the number of army hospital beds in the United States to more than 100,000. Medical officers are now being discharged from the army at the rate of from 500 to 1,000 per week. The army's

medical work in this country is performed almost wholly by members of the army medical corps, assisted to a slight extent only by "contract surgeons" and by civilian consultants. Nursing in the army hospitals is chiefly in the hands of army nurses who are graduates of civil hospitals, assisted by the enlisted men of the hospital corps. An army school for nurses, experimentally established in 1918, may or may not be continued. The use of nurses' aids or hospital assistants in the army hospitals was authorized during the latter part of 1918. Army nurses and nurses' aids are recruited chiefly through the Red Cross.

The hospitals supported by the states include mainly hospitals and asylums for the insane, psychopathic hospitals, hospitals for the feeble-minded, for the epileptic, for persons addicted to alcohol or narcotic drugs, and institutions for the blind, deaf and dumb, hospitals and sanatoriums for the tuberculous, penal hospitals, and in rare instances, general hospitals. The most important types of hospitals maintained by municipalities and counties are the following: general, chronic, contagious, tuberculosis, leprosy, pellagra, rabies, psychopathic, inebriate, emergency, alms-house infirmaries, and hospitals for ophthalmia and ringworm.

Voluntary or private hospitals may be classified according to the character of their support, as sectarian, non-sectarian, or racial; any of these may be either wholly philanthropic or semiphilanthropic. By far the largest group among the hospitals of a sectarian character are the hospitals of the Roman Catholic Church. "Sectarian" hospitals in the United States are strictly sectarian only in their control. In the application of their benefits and in their medical and nursing administration, nearly all hospitals in the United States are non-sectarian in some degree. Industrial hospitals, established in many instances as first-aid stations or emergency hospitals, have here and there achieved a high standard of excellence as general hospitals.

Hospitals are maintained by trade unions, by fraternal associations or "orders," and by insurance societies. Hospitals and sanatoriums for paying patients exclusively are conducted under medical cooperative proprietorship, under medical or nonmedical individual proprietorship, and by philanthropic organizations.

From the medical standpoint, voluntary hospitals may be broadly classified as "acute" and "chronic." Among the acute hospitals are the general hospitals, some of which assume the function of systematic medical teaching, while others ignore this function. "Staff" or "closed" hospitals are those in which patients are cared for

solely by an appointed staff, and to which medical men not definitely appointed may come only as unofficial visitors. "Open" hospitals are those to which any physician in the community may bring his patients for treatment by himself or under his supervision. In the larger cities and in the East, staff hospitals are favored; in smaller towns and in the West, open hospitals are prevalent. Both staff hospitals and open hospitals provide places for a resident staff of recently graduated physicians or interns, but at present the number of medical graduates is insufficient to fill the places that are available.

Among the more notable types of special hospitals in the acute class are the surgical, gynecological, eye, ear, nose, and throat, gastro-enterological, children's, and maternity. In the United States, hospitals for the care of contagious diseases are for the most part municipal in character, but contagious wards attached to general hospitals are increasing in number very rapidly. In New York City every hospital is required by the department of health to have one or more isolation wards in which contagious cases can be cared for.

Convalescent hospitals and homes may be attached to acute hospitals or may be quite independent. Even in the field of convalescence, medical classification is commencing to take place, and one finds today convalescent hospitals specializing in surgical convalescence, cardiac convalescence, in the treatment of neurotics, and in convalescence following maternity. Convalescent hospitals generally confine themselves to the treatment of either men, women, or children, but convalescent homes in which both sexes and all ages are treated are also known.

Hospitals for the treatment of chronic disorders include those maintained for the benefit of chronic and incurable invalids generally, and those of a special type. Homes for the aged and infirm are akin to and sometimes combined with hospitals for chronic and incurable invalids. The special chronic hospitals, medically classified, are hospitals for the insane, psychopathic hospitals for the near insane; hospitals for the neurologic, epileptic, and diabetic cases; hospitals for the treatment of obesity, tuberculosis, venereal and skin diseases, cancer; hospitals for orthopedic, paralytic, narcotic and alcoholic patients; hospitals or asylums for the blind and deaf; health resorts or sanatoriums; therapeutic institutes for physical therapy generally or for radium treatment; and the so-called preventoriums, designed especially for the constitutional up-building of undernourished children and for the temporary isolation and the development of the powers of re-

sistance of children who are exposed to communicable forms of tuberculosis.

In a compilation completed in 1918, the statistical department of *The Modern Hospital* included 7,158 general and special hospitals, with a total capacity of 657,965 beds. Of this number 542 were hospitals and asylums for the insane, capable of caring for 282,937 patients. The next largest group consists of general hospitals, of which there were said to be 4,716 with a capacity of 263,815 beds. Tuberculosis was credited with 488 hospitals and 38,584 beds; contagious diseases with 164 hospitals (probably an incomplete figure) and 17,324 beds; and ten other principal classes with from 8,000 to 2,000 beds each. The distribution of hospitals and hospital beds is far from uniform. Omitting beds in hospitals for the insane, California has about four times as many beds in proportion to population as Alabama, Massachusetts four times as many, New York nearly four times as many, Pennsylvania three times, Kansas and Virginia about twice as many. The proportions, however, are constantly changing.

We have already glanced at the movement for the improvement of dispensary service. Parallel with this is the movement for the establishment of minimum standards of efficiency and morality or fair play in hospital work, to which notable contributions have been made by the American Medical Association, the American Hospital Association, and the American College of Surgeons directly, and by the Rockefeller and Carnegie foundations indirectly.

Before 1905 social service in connection with hospitals was sporadic, individual, and accidental, "based on a very natural impulse to treat the individual as well as the disease." Since 1905, the need of organized social service adapted specifically to the treatment of disease has been generally recognized, and there have been established in the United States nearly two hundred hospital social-service departments. More than forty institutions are represented in the Hospital Social Service Association of New York City alone.

Cost of Medical Care

An outstanding feature of the situation in this country is the fact that the actual cost of private medical and hospital care is beyond the reach of the great bulk of the people, who are consequently compelled to accept such care either in whole or in part as the free gift of the state or of some philanthropic society and of the medical profession. It is with the greatest reluctance that self-respecting American citizens who are able to pay their way in health turn to philanthropic organi-

zations for relief in time of sickness, and one of the pressing questions of the day is how the hospital needs of this class can best be met. Shall it be assumed that the present economic status of the great majority of the people cannot be altered for the better? If so, is it not incumbent upon the state speedily to organize some system by means of which an adequate medical service will be supported in part, perhaps, by taxation, in part by employers, and in part by the workers themselves? Or, should the medico-economic reformer throw his support to the trade union movement, in an endeavor to secure such a readjustment of wages as will place the whole working population beyond the need of state-regulated, compulsory health insurance or of organized relief in any form whatever in time of sickness?

A Look Ahead

The agencies engaged in the care of the sick in America are legion. Is the service they are rendering all that is desired or that can reasonably be expected? Is the work distributed among the several agencies in due proportion to their material resources and their ability? Should private philanthropy be encouraged to extend its hospital, dispensary, and nursing work, or should it be supplanted by instrumentalities created, supported, and controlled by the state? Leaving out of consideration for the moment foreign countries with their peculiar conditions, traditions, and needs, is it best in our own United States to go on as we have been going, with a minimum of coordination, an almost total absence of community planning, and a maximum of private initiative and endeavor, or is it desirable to provide more coordination and even centralized administration?

President Wilson, to whom an appeal was made as recently as November, 1918, to get behind the movement for the establishment of a national department of health, expressed the opinion that the present was not an opportune time to urge upon Congress the expense and elaboration of such an instrumentality; he did not, however, say, nor has anyone in authority recently said, that the proposal is essentially unsound.

Sooner or later, in all probability, there will be a national department of health. What should be its scope? Should it confine itself to measures for the prevention of disease, or should it consider also the medical needs of the civilian population? Should the department aim chiefly at popular education in hygiene, or should it undertake the control and organization of medical and nursing practice? Should it at least seek to provide adequate medical and nursing service to the population in backward and neglected communities?

These are not academic questions. They are questions which those who are concerned for the efficiency of medical practice and medical administration in this country will seek to answer as a professional duty.

One of the pressing needs of the country today is a scheme of medical administration much broader in scope than any program of health insurance yet proposed. To promise success, such a scheme must, in my opinion, be elastic as well as comprehensive. It must regard the economic needs of the physician as well as the economic status of the patient. Above all, it must recognize the fundamental fact that medicine is a profession, not a trade. To free the physician from the fetters of commercialism and then bind him in the chains of bureaucracy would be a calamity.

In the future, the state may provide the doctor's office, it may guarantee all or part of his income, but it should leave him free to think and to act, to study and to serve.

MALINGERERS IN THE DRAFT

The problem of malingering as it appears in the army draft was tersely summed up by the Provost Marshal General in his second annual report, as follows:

"Malingeringers may be divided into three general groups:

"(a) Real malingeringers with nothing the matter with them, who injure themselves, or make allegations respecting diseases or such conditions as drug taking, or who counterfeit disease with full consciousness and responsibility; all for the purpose of evading military service. Many of these have been coached.

"(b) Psychoneurotics, who are natural complainers and try to get out of every disagreeable thing in life. Perhaps only partially conscious of the nature or the seriousness of what they do and only partly responsible. In many the motives are not persistent. . . .

"(c) Confirmed psychoneurotics with long history of nervous breakdowns and illnesses who behave like class (a), but more persistently, and from whom not much can be expected in the way of reconstruction.

"Men shoot or cut off their fingers or toes, practically always on the right side, to disqualify themselves for service. Sometimes they put their hands under ears for this purpose. Many men have their teeth pulled out. Retention of urine is simulated. Egg albumen is injected into the bladder or put in urine. Glucose is added to urine. Digitalis, thyroid gland preparations, and strophanthus are taken to cause disturbance of the heart, and cantharides to cause albuminuria. The skin is irritated by various substances, which are also injected under it to create abscesses. Various substances are taken to bring about purging. An appearance of hemoptysis may be produced by adding blood, either human or that of animals, to the sputa. Sometimes merely coloring matter is added. Those who can vomit voluntarily what they swallow use the same means to create the appearance of hematemesis. Similarly, coloring matters may be added to the stools. Mechanical and chemical irritants are made use of to cause inflammation about practically all the body orifices. Jaundie may be simulated by taking pueric acid. Crutchies, spectacles, trusses, strappings, etc., are made use of to create the appearance of disability."

THE INTERPRETATION OF THE DEATH RATE BY CLIMOGRAPHS

BY ELLSWORTH HUNTINGTON, PH.D., RESEARCH ASSOCIATE IN GEOGRAPHY, YALE UNIVERSITY, NEW HAVEN, CONN.

ALMOST everyone realizes the supreme importance of the right kind of air; but our ideas of what is really right are still hazy. A dry climate, for example, is generally supposed to be better than a moist; cold waves are thought to do much harm in winter; and a uniform climate with the right temperature is assumed to be better than one subject to pronounced variations. These are regarded by the layman as well established principles, and are generally accepted by physicians. Yet a study of deaths in a score or more countries suggests that they are fallacious.

During the past few years I have examined the relation of about sixty million deaths to temperature and humidity. Nearly nine million of these deaths were studied intensively, that is, the deaths in each of 80 cities, during a period of ten to fifteen years, were compared with the temperature and humidity of the month when they occurred. The records for each place were first tabulated independently so that there was no chance for error because of differences in occupation, race, habits, and so forth from city to city. Moreover, epidemic diseases were treated separately on a scale large enough to show that in the long run their relation to climate is in most respects the same as that of other diseases, while their number is too small to affect our final results. In addition to this, about 400,000 deaths in New York City were treated still more minutely, a comparison being made between the number of deaths and the weather each day for eight years. Surprising as it may seem, the immediate response of health to the weather from day to day is almost as important as the response to the seasons. Thus the response to weather conditions, both seasonal and daily, appears to be overwhelmingly the most important of all elements in the problem of general health.

To sum up the whole matter: a general study of

People of all races seem to have the best health at approximately the same mean temperature, 64° F. Apparently there is no such thing as acclimatization.

Cold waves are highly beneficial to health; continued cold, however, leads to increased morbidity. On this basis frequent use of a sudden but temporary drop of temperature would appear advisable as a therapeutic agent.

Alternations of temperature from warm to cool, and the reverse, appear to be decidedly favorable to health. Hence our practice of sending patients to uniform climates seems erroneous. We need to live out-of-doors in a moist, variable climate with a mean temperature of about 64°, but with many cold waves. In hospitals such conditions should be simulated.

ference, moist climates are correspondingly better than dry.

2. Cold waves, unless of extraordinary severity, are distinctly beneficial to health, while a rise of temperature even in winter is harmful. In considering this conclusion a careful distinction must be made between the effects of a *drop* in temperature, i. e., the wave itself, and of a *continuance* of a low temperature.

3. A variable climate is in general much more healthful than a uniform climate even though the latter has an almost ideal temperature.

The present article is too short to allow much discussion of methods, but a brief statement of how these conclusions were reached seems essential.*

In studying the nine million deaths where the month was the unit, 52 cities were chosen in the United States, 14 in France, and 14 in Italy, and statistics were collected for the years 1899 or 1900 to 1915, or as much thereof as possible. These cities were distributed so as to cover the whole of each country. For each city the deaths during each month were reduced to percentages of the normal for the place and year in question, thus facilitating the comparison of one city with another. The percentages were then grouped according to the humidity and temperature. For example, the percentages for all the months having a mean temperature of 60° and a mean hu-

about fifty million deaths, an intensive study of about nine million deaths by months for individual cities, and a still more intensive study of about 400,000 deaths by days in New York City, lead to the following three conclusions, which are at variance with the beliefs ordinarily accepted:

1. Fairly moist weather is almost invariably more healthful than dry weather of the same temperature, and, by in-

* For a full discussion of this matter and for a study of the relation of public health to business depressions, to great events of history, and to the evolution of species, see "World Power and Evolution," by Ellsworth Huntington, Yale University Press, New Haven, 1919.

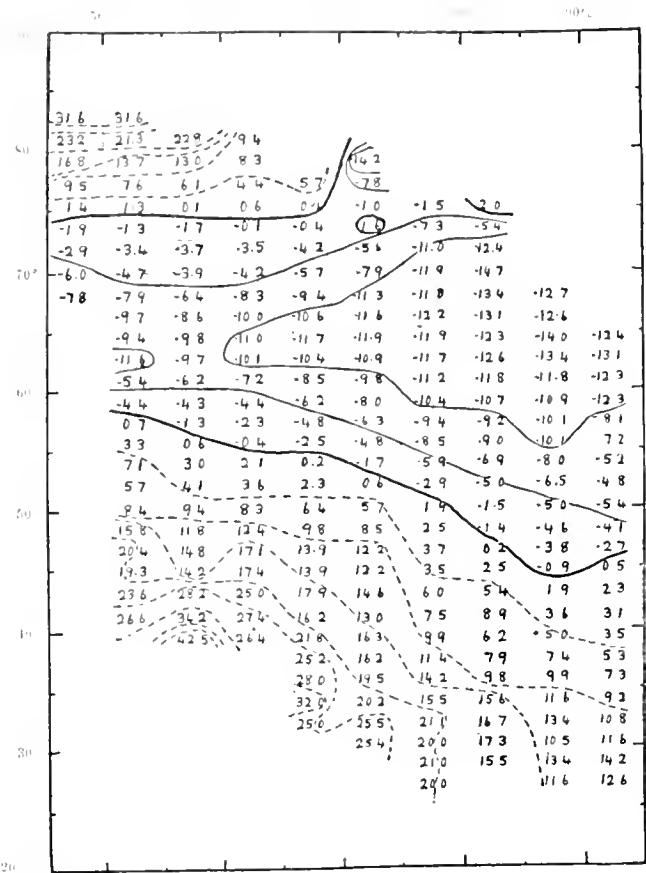

Fig. 1. Unsmoothed Climograph of France and Italy, 1899-1913,
3,700,000 Deaths.

midity of 75 per cent in the cities of a given region were averaged together, with allowance for the size of the cities. Thus during 15 years one city may have one such month, another three, another two, and so on, making a total of 15 records at perhaps seven different cities. The average death-rate may be 20 per cent of the normal, or a minus departure of 10 per cent. Again in the same region there may be nine records of months having a mean temperature of 40° and a mean humidity of 80 per cent, and the weighted average of the deathrate might be 109 per cent, or a plus departure of 9 per cent above the normal.

When a series of such averages had been obtained, the amounts by which they departed from the normal were plotted in a chart like Figure 1, which shows the conditions under which 3,700,000 deaths occurred in France and Italy. Each number in the "climograph," as such a chart is called, indicates the average departure of the deathrate from the normal under the climatic conditions indicated by the temperature figures at the side and the humidity figures at the top. Notice that the greatest negative departures, that is, the most favorable conditions, are found not far from the black dot which has been placed at a temperature of 64° and a humidity of 80 per cent. All the de-

partures of 10 per cent or more below the normal are included within the 10 per cent "isopraet," or "line of equal efficiency," which has been drawn according to the principles used in drawing isotherms on weather maps. Another isopraet has been drawn at -5 per cent, a heavy isopraet at zero, and others, the dotted lines, at 5 per cent intervals in the part of the climograph indicating climatic conditions where the deathrate is above normal.

Such climographs give a clear picture of the effect of climate. The difference between different cities plays no part, since each city is compared only with itself. The effect of epidemics is also eliminated except in rare instances, since not only do epidemics bear almost the same relation to climate as do other diseases, except as indicated later, but the averaging of a large number of cities and of a large number of years almost completely smoothes out the effect of all epidemics such as occurred during the years in question. For convenience, it is well to smooth the climographs, as

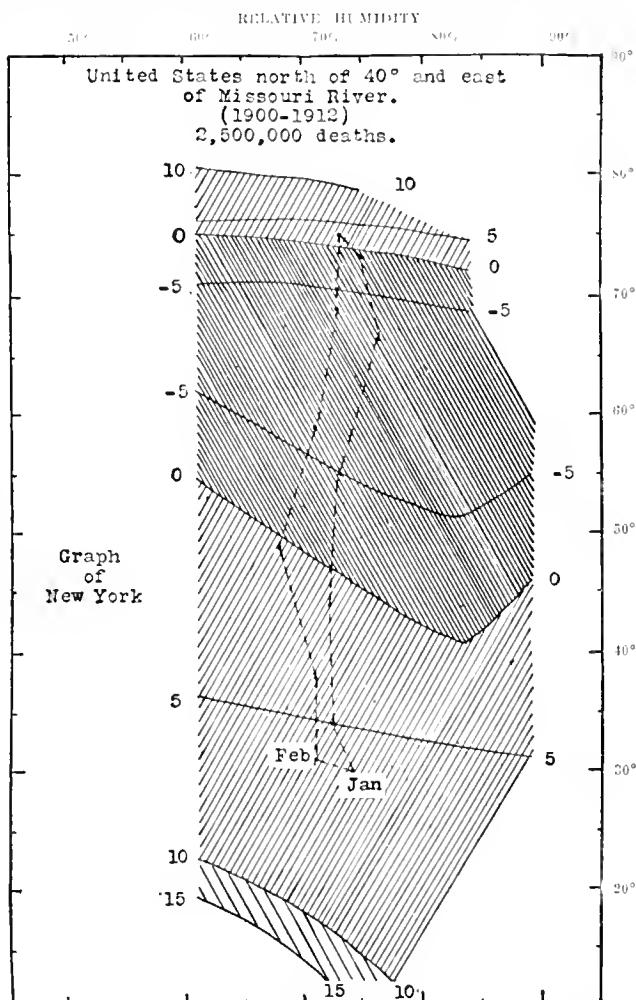

Fig. 2. Climograph of the North Eastern United States. The dash-line in the center shows the conditions of temperature and humidity in New York City for January, February and so on through the year. (Temperature F.)

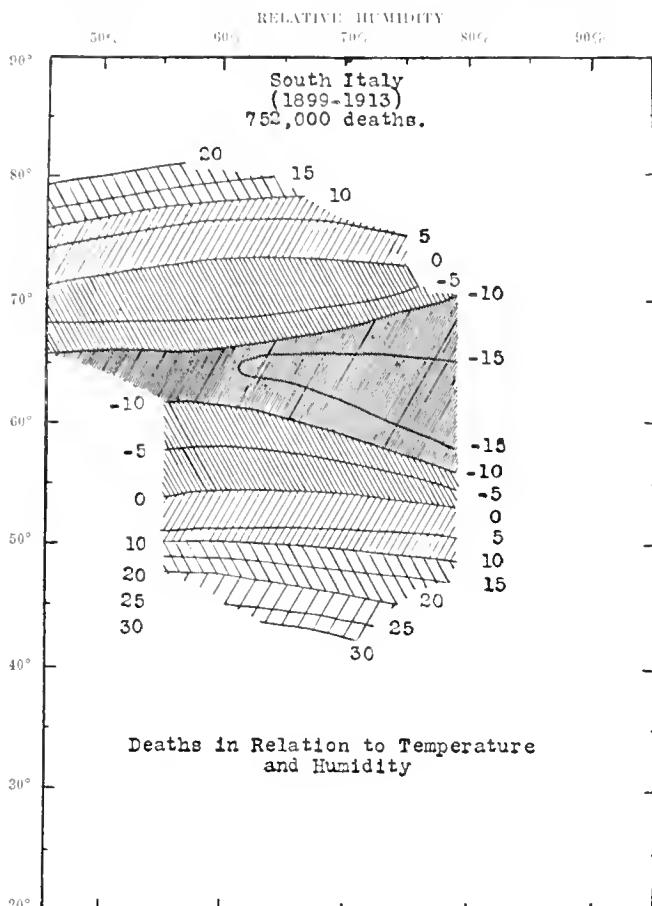

Fig. 3. Climograph of Southern Italy. (Temperature F.)

has been done in Figure 2, representing the northeastern United States, and Figure 3, representing southern Italy. In these climographs the heavy shading indicates good health, the light shading poor health, and the absence of shading means that there are no months having the combinations of temperature and humidity indicated by those particular parts of the chart.

Results

Ideal Temperature.—Let us now consider what results are derived from a series of climographs representing about nine million deaths, and from supplementary studies of fifty million more. The most conspicuous result is that in all parts of the world the most favorable or "optimum" temperature is practically the same. In other words, there appears to be almost no such thing as true acclimatization. Whether we take Sicily or Sweden, Florida or Maine, the general health is best when the temperature averages about 64°F., that is, when the thermometer falls to about 55° or 60° at night, and rises not much above 70° at noon. Moreover, race seems to have almost as little effect on the optimum as does place. When the climograph of about 167,000 negroes in the northeastern United States for the

years 1912 to 1915 (Figure 4), is compared with that of about 921,000 whites who lived in the same cities and died during the same years (Figure 5), the optimum temperature for the negroes appears to be only 4° higher than for the whites, and fuller data might reduce this. When Finns and Cubans, Scotch and South Italians, and Japanese, and various other races, are compared there is no essential difference. Yet the mean temperature, in the places where these various races live differs by 30° or even 40°. Thus it looks as if the relation of man to the outside temperature were almost as uniform as his relation to internal temperature. In fact, one is led to query whether the uniformity of the temperature of the human body among all races and in all climates may not be the reason for an almost equally marked uniformity in the temperature at which man's physical efficiency is highest.

If this is so, it has an important bearing on the problem of the heating of our houses in winter, the cooling of them in summer, and the possibility of raising the people within the tropics and in

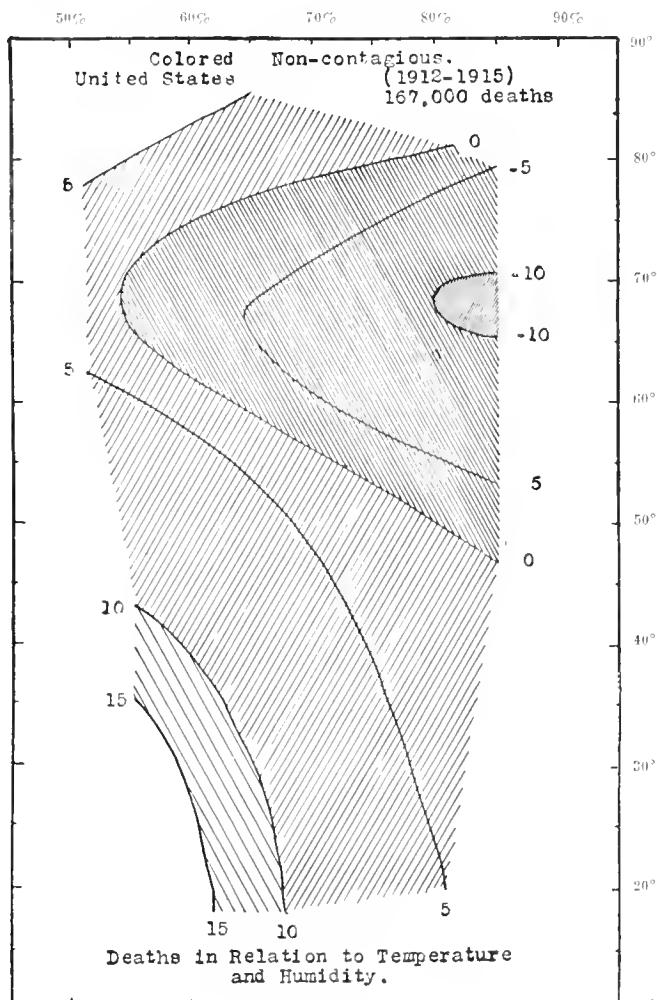

Fig. 4. Climograph of Colored Race in Eastern United States. (Temperature F.)

northern countries like Alaska to as high a level as those of more favored lands. In this connection, however, two other most important considerations must be borne in mind. First, the mean temperature is only one of the three main climatic elements, the others being relative humidity and the variability of the temperature. Second, while physical health seems to be best at a mean temperature of about 64° F., various investigations indicate that the mental optimum is considerably lower, perhaps no higher than 40°.* Thus since man is much more able to warm his body than to keep it cool, the countries and seasons that are cooler than the optimum have a great advantage over those that are even a little too warm.

Ideal Humidity.—Man's response to the humidity of the air seems to be almost as uniform as his response to temperature. In practically all of our climographs the best conditions seem to be when the temperature averages 64° and the relative humidity is not far from 80 per cent for day

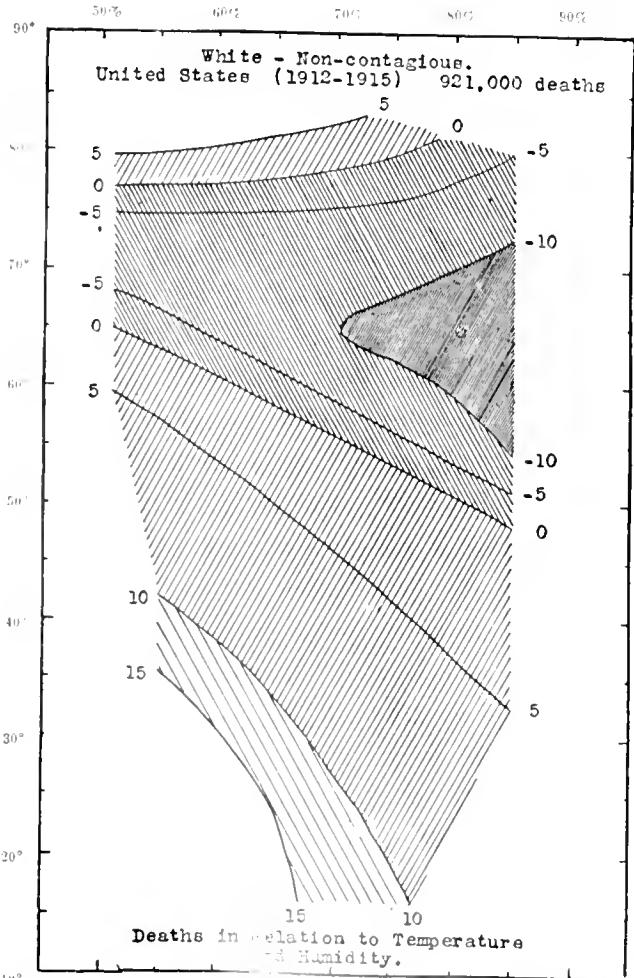

Fig. 5. Climograph of the White Non-contagious Race in the Eastern United States. (1912-1915).

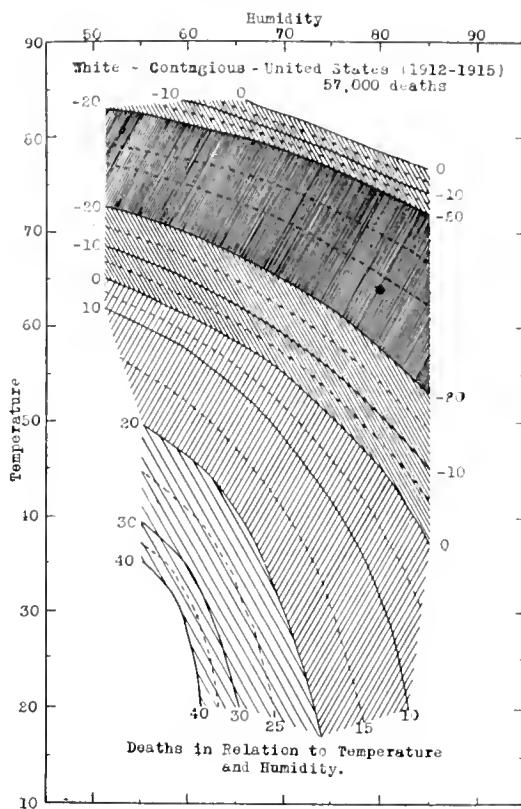

Fig. 6. Climograph of White Race; Contagious Group.

and night together. This means that by day the humidity may fall as low as 60 per cent while at night the air may become so damp that dew falls. In general this degree of humidity is decidedly greater than that which is generally supposed to be most favorable. There can scarcely be much doubt as to the facts, however, for in almost every one of the climographs representing our nine million deaths there is a tendency for the isopracts to converge toward the left. In other words, when the temperature is ideal people's health is best with a mean humidity of about 80 per cent as indicated by the black dot on the climographs, while in the drier weather, which is usually considered beneficial, the death rate increases. This seems so contrary to our usual beliefs that we are loath to accept it. The explanation of the apparent discrepancy, however, probably lies in the fact that when the air is dry people spend more time out-of-doors than when it is wet. The out-of-doors life does much to improve health, and we wrongly attribute this to the dryness.

An interesting example of this was seen at Camp Shelby, Miss., last winter during the influenza epidemic. The camp normally had beds for 1,300 patients, but 1,800 were sick at one time. The surplus had to be accommodated in tents hastily erected on muddy ground. The weather was wet and dismal much of the time. Yet, to

* This matter is discussed in "The Relation of Weather to Health and Climate," by Ellsworth Huntington, Yale University Press, New Haven, 1915, pp. 77-82 et al.

the surprise of the physicians, as I learn from Dr. Todd, the patients in the wet tents fared better than those in the regular hospital. Further details of this impromptu experiment ought to prove most illuminating.

At high temperatures the relation of humidity to health is about what is ordinarily supposed. Japan, for instance, affords a striking example of the ill effect of great humidity at high temperatures, for the death rate in August and September at the end of the warm, wet summer is very high. On the other hand, in the United States the figures show unmistakably that warm dry weather does more harm than warm wet weather. This is true even in the northeastern United States. At high temperatures either extreme of humidity is bad.

An interesting exception should be noted at this point. Figure 6 is the climograph for deaths from contagious diseases in the same cities for which the deaths of negroes and whites from non-contagious diseases are shown in Figures 4 and 5. The number of deaths is relatively small, only 57,000, but it is large enough to suggest that in warm weather there is a real difference between contagious and non-contagious diseases in their relation to humidity. With a relative humidity of 85 per cent the optimum temperature for the prevention of contagious diseases appears to be about 65°, but as the humidity diminishes the optimum rises until it becomes about 78° in weather so dry that the mean humidity falls to about 50 per cent. This agrees with the usual supposition as to the relation of humidity to health, but re-

member that it applies only to contagious diseases which for the years and cities used in Figures 4 to 6 amounted to only about 6 per cent of the total. The difference between Figures 5 and 6 suggests what interesting results will be obtained when climographs are prepared for specific diseases.

A beginning along this line has been made by Dr. David Greenberg, of the Yale Medical School. He finds that in pneumonia the relation to humidity is the same as that shown in the climographs of this article, while the incidence of the disease diminishes in direct proportion to the rise of temperature.*

Turning now to low temperatures we find the most marked effect of humidity. Notice how the isopcharts in the lower parts of Figures 1, 2, 4, 5, and 6 slope downward from left to right. This means that in dry winter weather there are many more deaths than in damp winter weather of the same temperature. For example in Figure 1, at a temperature of 40° and a humidity of under 65 per cent the deathrate is fully 20 per cent above the normal; while at the same temperature with a relative humidity of 85 per cent or more, the deaths are only 5 per cent above the normal. This is so surprising that one is inclined to doubt it, or at least to suspect that some other factor is operative. Can the season at which dryness occurs have anything to do with causing dry air to appear so harmful? For example, December has a relatively low deathrate in proportion to its tem-

* More deaths in dry weather than in wet

perature because the good effects of the highly favorable autumn conditions hang over somewhat; while February has a high death rate because it comes toward the end of the long, trying winter. If December were regularly damp and February regularly dry, damp weather might appear favorable simply because it comes early in the winter.

As a matter of fact there is no such relation between humidity and the seasons. Nevertheless the matter is so important that I have tested it carefully. Table 1 shows the departure from the normal death rate in five large American cities. The 15 years from 1900 to 1914 have been divided into three 5-year periods. For each period and each city the wettest and driest December, January, February, and March, respectively, have been selected. The percentage by which the mortality of each month departs from the normal is given in the table. The asterisks indicate cases where the dry months had more deaths than the wet. Such cases number 39 against 21 of the other kind. The two right hand columns show that for the five cities as a whole the dry months had more deaths than the wet except December for the periods 1900-1904 and 1905-1909. Yet when all the Decembers are averaged together the dry months are a little worse than the wet. These would be still more the case if allowance for temperature were made as is done below.

In the line of Table 1 marked "Average" the figures for all the winter months at each city have been combined. Except in St. Louis more deaths occurred in dry months than in wet appears in the line marked "Apparent advantage of wet over dry." Even St. Louis, however, is not really an exception, for the wet months happened to have a mean temperature of 36.0° as appears in the line marked "Average Temperature," while the temperature of the dry months was 38.9°. In order fairly to estimate the effect of aridity we must increase the mortality rate of the dry months to the level that it would have reached had the dry months been as cold as the wet months. During the 15 years from 1900 to 1914 St. Louis experienced 35 months with a mean temperature of 35° or less. They averaged 31 and their mortality was 9.1 per cent more than the normal. During the same period there were 34 months whose average temperature ranged from 37° to 49°. Their average was 43 and their mortality 3.2 per cent above normal. Thus a difference of 12° in mean temperature was correlated with a difference of 5.9 per cent in mortality. On this basis we may correct the mortality for the dry months in St. Louis and eliminate the effect of the difference in temperature between the wet

months and the dry. The figures for mortality thus become: dry 7.6 per cent and wet 6.9 per cent, which agrees with the other cities. In the line of Table 1 marked "Real advantage of wet over dry, etc., " a similar correction has been applied to all five cities. The average advantage of wet over dry is summed up in the figure 3.5 per cent at the right hand end of the line. This means that when due allowance is made for temperature, a difference of 10 per cent in humidity is correlated with a difference of 3.5 per cent in the death-rate. A similar relation prevails no matter which of the winter months is employed. It also prevails in other cities and other countries. Moreover, when the windiest and least windy months, or the stormiest and least stormy, are compared according to the method employed above, no clear evidence has yet been found that these conditions have any such marked and uniform effect upon the death rate. Further investigation may show that the variability of the temperature from day to day is greater in wet months than in dry, and this may enter into the problem, but thus far this has not been found to be nearly so important as humidity. Thus it appears that the excess of deaths in dry months is really due largely to the dryness.

This conclusion leads to far-reaching consequences. If dry air is harmful at the optimum temperature, as it unquestionably is, it suggests that our practice of sending patients to dry climates ought to be modified, except in special diseases, such as those which make Figure 6 exceptional. Still greater changes in our habits are demanded by the fact that in winter the dryness of the air is accompanied by an increase of from 10 to 40 per cent in the death rate. It is worth noting, however, that in some regions such as southern Italy, as shown in Figure 3, there is no increase in deaths because of dryness in winter. Similar conditions prevail in Tokio, Japan, and to a less degree in southern California. None of these places, however, is particularly cold in winter, and in none are the houses heated to any great extent. Wherever the houses are heated, on the other hand, the evil effects of dryness are only too apparent, as appears in Figures 4 to 6. The obvious conclusion would seem to be that in our hospitals and sick-rooms we are killing thousands of people each winter because we keep the air as dry as that of deserts; and at the same time we are filling our hospitals by keeping our houses too dry. Out-of-doors the winter air is moist enough, but when heated it becomes so dry that it has a devastating effect upon the delicate mucous membranes. The average humidity ought to be as high as 80 per cent. This is true not only of hospitals,

but of the rooms where people in good health work and play and sleep. But so high a degree of humidity is uncomfortable, the objector will say. Yes, if the thermometer stands at 70° all the time, but suppose it averages 64°, as it ought if we may judge from our nine million deaths. In that case

1 for France and Italy combined they begin to be nearer, while in Figure 3, representing south Italy, they are very near. Where the isopraacts are near together it means that people are sensitive to any departure from the optimum temperature; where the lines are far apart peo-

the humidity will fall to perhaps 60 per cent when the temperature approaches 70°, and will increase when the rooms become cool at night. That is what ought to happen, apparently, for those are the conditions under which the general health of the community is best.

The Value of Variability.—This brings us to the most important because the most neglected part of our subject. For generations the ordinary practice has been to keep our houses and especially our sick-rooms at as uniform a temperature as possible. To a certain extent this has begun to be modified, but it is still widely prevalent. Yet our study of deaths seems to indicate that such a practice is wholly wrong. The evidence for this may be divided into three parts: (A) a comparison of the effect of variations of temperature in different climates; (B) a detailed study of the effect of variations of temperature upon health day by day in New York City; and (C) a study of the effect of variability upon the health of school children in New York City.

A. Variability in Different Climates

Compare the climographs shown in Figures 1 to 5. In Figure 2 for the northeastern United States the isopraacts are far apart; in Figures 4 and 5 for the Eastern United States from 1912 to 1915 they are still far apart, although not quite so far as in Figure 2. Next in Figure

ple are easily able to resist either heat or cold. All the climographs on which this article is based are consistent in this respect. Slightly cool weather in Los Angeles, for example, does more harm to health than decidedly cold weather in New York.

Where the climate is highly variable from season to season people acquire a fund of reserve energy which makes them easily able to resist extremes. When they go to uniform climates like California they are unquestionably benefited at first, for they not only enjoy a stimulating change but go to a place where the temperature is almost ideal—that is, not far from 64°. Their health improves just as does that of most communities in the autumn. Yet when they stay in such climates they become more and more sensi-

TABLE III.

Changes of the deathrate
on 100 days with the greatest drop of temperature
compared with changes in the deathrate on a hundred days
with the greatest rise of temperature.

	Autumn	Winter	Spring	Summer

Difference	9.1%	10.4%	19.3%	23.4%

tive to changes; their power of resistance diminishes; and in the end their chances of long life seem to be lessened. The presence of invalids

and health seekers does not enter into the matter, being few in the cities of our primary study.

B. Health and Daily Variation of Temperature in New York City

In order to determine the real relation of variability of temperature to health I have made a detailed study of the daily deaths in New York City for the years 1877 to 1884. These years were chosen simply because, incredible as it may seem, no records of daily deaths appear now to be kept in any part of the United States. Yet, as will shortly appear, such records are quite as important as records by months or years. In fact for many purposes they are even more important. The method of investigation is as follows: for each day two conditions were tabulated, namely the change in the number of deaths and the change in the mean temperature. The deaths, for example, might number 100, 110, and 97 on three successive days, while the temperature might be 44°, 50°, and 42°. The change in deaths from the first day to the second would be +10, and from the second to the third -12, while the changes in temperature were +6 and -8° respectively. When all the days with a given rise or drop of temperature were averaged together the corresponding changes in the number of deaths were found to be as in Tables 2 and 3.

These two little tables are of the utmost significance. They represent about 400,000 deaths divided into about 2,900 groups corresponding to the days of eight years. This is a basis broad enough to give conclusive results, especially when practically every single month shows the relationship that is so apparent when averages are computed. Study Table 2 a minute. Column A shows the change in mean temperature from one day to the next; column B the number of days with a given change in the autumn; C the percentage by which the deaths on the days indicated in B exceeded or fell short of those on the days immediately preceding; and so on. Run the eye down columns C, E, G, and I. Notice that invariably the days characterized by a marked drop in temperature show also a marked drop in the death rate; the days with little or no change in temperature show little or no change in deaths; and those with a marked rise of temperature show a marked increase in deaths. In column C, for autumn, the change from the uppermost to the lowermost figure is slightly irregular, but unmistakable; in column E, representing the winter, it is almost regular; while in columns G and I, for spring and summer, it is absolutely regular.

In Table 3 the same fact is brought out in an-

other way. Here for each of the four seasons approximately a hundred days, or the seventh of the time having the greatest drop, and another hundred having the greatest rise of temperature, have been chosen. Notice how regularly the deathrate decreases with a fall of temperature and rises when the weather becomes warm. Notice also the magnitude of the differences between the two groups of days in each season. A difference of over 9 per cent in autumn and 10 per cent in winter is enough to be of great significance, while a difference of 19 per cent in spring and 23 per cent in summer is truly astounding. Such differences mean that as a steadily operating cause of fluctuations in the deathrate variations in temperature from day to day are perhaps the most potent agency yet discovered. They also mean something still more surprising, namely, that a drop in temperature is beneficial *at all seasons*. It is less beneficial in winter than in summer, to be sure, but perhaps that is merely because its effect is partly nullified by the way in which people shut themselves up in the house in the cold season. At any rate, the fact is unmistakable that in New York City during a period of eight years the one-seventh of the days having a great drop of temperature were on an average about 15 per cent more healthful than the seventh having a great rise of temperature.

In considering this matter the effects of a *drop* in the temperature and of a *continuance* of low temperature must be sharply distinguished. If the temperature *stays* low, the deathrate increases markedly. Only the actual drop is beneficial. The case seems closely analogous to a cold bath. The first plunge is highly stimulating, and one emerges warm and invigorated, but if the bather stays in the water long enough to become chilled, he emerges cold and weak. On the other hand, a warm bath, like a warm wave, is relaxing and enervating. Each may have its uses, and in the case of the weather a warm wave may lead to conditions that are excellent, but in itself it is harmful.

In view of these facts the question arises whether highly variable weather is beneficial, or whether the effects of changes toward lower and higher temperatures balance one another. In order to test this I have divided each of the eight years 1877 to 1884 into 24 periods of half a month each, and have then determined the average relation of daily changes of temperature to health in New York City at all seasons. Without going into details it may be said that in Table 4 the plus signs mean that the health of New York was better after periods of ten days with a high degree of climatic variability than after periods with a

slight degree of variability. In 20 semimonthly periods out of 24 the better health follows the more variable weather. In the four periods showing the opposite condition the departures from zero are too slight to be significant. It should be noted that they occur at the time when the general

succeeding rise in temperature is considered, the net benefit of such changes is at least 6 or 7 per cent and perhaps much higher. Surely it may be said that such changes of temperature, if rightly applied, might have a most helpful therapeutic effect.

TABLE IV.

Percentages by which the variability of the temperature from day to day in periods preceding the best health differs from the variability in similar periods preceding the worst health. (Smoothed.)

January 1-15	+ 2.3%	April 1-15	+ 3.7%
January 16-31	+ 3.2%	April 16-30	+ 5.1%
February 1-14	+ 2.7%	May 1-15	+ 5.8%
February 15-28	+ 2.8%	May 16-31	+ 6.0%
March 1-15	+ 3.4%	June 1-15	+ 4.9%
March 16-31	+ 4.0%	June 16-30	+ 3.6%
Average . . . + 3.1%		Average . . . + 4.9%	
July 1-15	+ 3.4%	October 1-15	+ 0.1%
July 16-31	+ 4.3%	October 16-31	- 0.2%
August 1-15	+ 7.2%	November 1-15	- 0.2%
August 15-31	+ 6.8%	November 16-30	- 1.0%
September 1-15	+ 4.7%	December 1-15	- 0.8%
Septem'r 16-31	+ 0.7%	December 16-31	+ 1.1%
Average . . . + 4.5%		Average . . . - 0.2%	
GRAND AVERAGE . . . + 3.1%			

health of the community is highest, and at the time when cold waves have the least effect, as appears in Table 2. From all this it appears not only that cold waves at all seasons are highly beneficial provided the cold weather does not continue, but also that, in general, people's health is good during periods when there are frequent and extreme changes of temperature.

The lesson of all this is obvious. We have had the habit of trying to preserve a uniform temperature for well people and still more for the sick. That appears to be the worst possible policy. Perhaps in some diseases it may be helpful, but for the great majority the contrary is clearly the case. What we ought to do is to make the temperature vary as much as possible, up to the limit that people can stand without becoming chilled.

Indeed, we ought perhaps to pay special attention to the stimulating effect of changes of temperature when a disease reaches a critical stage.

I know that this sounds revolutionary, but remember that in New York in spring and summer, when the outside temperature corresponds to that of an ordinary sick room, a drop of 10° or more in temperature is accompanied by an improvement of over 20 per cent in the death rate. Moreover, even when the neutralizing effect of the

C. Variable Temperature and the Health of School Children

Even if the reader is inclined to accept this conclusion, he naturally asks for experimental proof. The answer is that no experiments appear to have been tried on a large scale with this particular purpose in mind, but the New York Ventilation Commission has tried an experiment which unintentionally fills the bill. The Commission's purpose was to test the value of window ventilation compared with the most approved modern

TABLE V.

Effect of Variability of Temperature upon Respiratory Diseases among School Children in New York.

Character of Room	Absences due to Respiratory Diseases per M Possible Attendances	Respiratory Diseases per M among Pupils in Attendances
(1) Cool rooms (60°) with window ventilation	9.6	59.4
(2) Warm rooms (68°) with window ventilation	10.4	37.5
(3) Warm rooms (68°) with fan ventilation	13.5	88.8

systems of artificial ventilation. During the period from February 19 to April 8, 1916, records of diseases of the respiratory organs were kept

in eight New York schools having 58 class rooms, and 2,541 pupils, while from November 4, 1916, to January 27, 1917, similar records were kept in 12 schools having 76 rooms and 2,992 children. A corps of trained nurses under the supervision of physicians examined the children daily and looked up those who were absent. The rooms were divided into three groups: (1) cool rooms where the windows were kept open as much as possible and the temperature averaged about 60 most of the time; (2) warm rooms having no ventilation except by means of windows; and (3) warm rooms provided with artificial ventilation by means of fans. The children of the three groups were of the same kind and in each case came from practically all grades of society. So far as purity of the air was concerned the rooms of group 3 had an advantage, since they received a constant stream of pure, fresh, warm air, while the others received fresh air more or less intermittently according to the amounts that the windows were open. Judged by the ordinary standards group 3 had a distinct advantage. Yet look at the results as given in Table 5.

I have headed this table "Effect of variability of temperature" because this appears to be the only difference that can account for the great advantage of group 1 and especially of group 2 over group 3. The children of group 3, with fan ventilation and hence with uniform temperature, had 3.9 more absences per thousand and 29.2 more colds per thousand than the children of group 1 in the cool, but variable room. The rooms of group 3 were about 4° warmer than the optimum according to our nine million deaths, while those of group 1 were about an equal amount too cool. If we assume that these two departures from the optimum balance each other, the only apparent difference is in variability. When groups 2 and 3 are compared the contrast is still more striking, and there is no difference of mean temperature to confuse the issue. The only difference in the air of these two groups was that in group 3 the air was never allowed to get much above or below 68°, while in group 2 it sometimes became too warm and then was suddenly cooled a few degrees by opening the windows. Yet this small difference in variability seems to be correlated with an advantage of 3.1 per thousand in absences because of sickness, and 51.3 in colds among the pupils in attendance. Thus in both cases variability appears to be a great advantage. If these facts stood by themselves we might question this conclusion, but when they are viewed in the light of our study of the effect of variability upon the daily deathrate in New York City as a whole, the case seems fairly clear.

Here we must leave the matter. Our study of deaths seems to indicate that both in our homes and still more in our hospitals certain radical changes are necessary. First, the mean temperature should average about 64° rather than about 68° or even 70° as is now often the case. Second, the relative humidity should be considerably higher than now, especially in winter. Third, there should be constant variability of temperature, the degree of change and the level to which the temperature should drop to be determined by the patient's power of resistance. If the ideal system were employed the temperature would presumably range every few hours from perhaps 58° to 70°, with an average of 64°. It begs the question to say that this would be too variable for the average patient. Of course, it would if the patient had previously been kept in a uniform and enervating temperature of 70°. But even in that case it would be possible to let the temperature range back and forth from perhaps 62° or 64° to 70° and then gradually increase the range and lower the average until the ideal was reached. It goes without saying, that we are only at the beginning of this subject. This much, however, is certain: the millions of deaths for which statistics are available are an enormous and almost untouched reservoir of facts as to the preservation of health. So far as that reservoir has been tapped, it seems to indicate that some of our most cherished ideas of the relation of health, temperature and humidity are wrong. We must follow the leading of the facts, and meanwhile test them more minutely and in many other ways.

Schoolmasters Urge Hygiene Program

The National Education Association at the meeting of the Section of Superintendence, in Chicago, presented the report of the Commission on the Emergency in Education in which the commission urged medical and dental inspection of school children, the establishment and supervision of playgrounds, gymnasiums, swimming pools and athletic fields, school lunches, clinics, open-air schools, school farms and gardens, not only for the city but for the country as well.

Improper Home Hygiene as Cause of Rickets

The three principal causes of rickets among children of industrial populations, according to Leonard Findley, a contributor to the *Glasgow Medical Journal*, seem to be improper housing, absence of facilities for open-air life, and imperfect parental care. These factors, in the order stated, he found to be the primary cause of the trouble in a statistical study of the family environments and dietary conditions in the homes of 500 rachitic children. The average air space per person among the families most afflicted was 122 cubic inches. Among the group only mildly afflicted the average air space was 483 cubic inches, while among the nonrachitic families, it was 625 cubic inches. Ventilation, home sanitation, and the absence of open-air spaces and playgrounds were determining factors.

THE PHYSICIAN'S OBLIGATION TO THE PUBLIC HEALTH

BY RUPERT BLUE, SURGEON GENERAL, UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

TO the credit of the medical profession be it said that, though physicians gain their living principally through the prevalence of disease, they have ever been active in seeking to control, prevent, and eradicate this foe of mankind.

With the extensive social and economic adjustments now going on throughout the world, the time has come for physicians generally to take a more active interest in determining the relation of medicine to the public health and welfare. Unfortunately, many physicians apparently do not realize how they can participate in this important work. It may not be amiss, therefore, to enumerate what the community may legitimately expect of physicians. As I conceive his obligation to society, the physician should apply his special knowledge to the study of community health problems and make himself one of the leaders in the inauguration of measures to promote public health and welfare.

To do this he must maintain active contact with the agencies engaged in the promotion of health and welfare; keep informed regarding recent important activities and achievements in the field of public health and state medicine; interest himself in the interrelation of health and social and economic conditions, and cultivate a broader outlook on the relation of medicine to public health and welfare; constitute himself a health educator, always to his patients, and as occasion offers, to the community; seek to discover the causative factors in disease and direct attention to their correction or removal; cooperate whole-heartedly with the health authorities by promptly reporting all births and deaths and all cases of notifiable disease, by assisting in the maintenance of quarantine, by promoting preventive measures for the control of disease, and by utilizing the diagnostic laboratory facilities and specific therapeutic agents offered by the health authorities.

It is almost inexcusable for a physician to be ignorant of the sanitary condition of his community. Thus, he should know the source of the

IF NOT, WHY NOT?

Do I fully instruct patients in controlling the spread of communicable disease?

Do I stimulate the people of my community to initiate community health work?

Do I always seek to discover the underlying social and economical causes of my patients' illness?

Do I place self-interest above community welfare by failing to report communicable diseases to the health officer?

Do I strive to keep public health matters out of partisan politics? Do I keep abreast of progress in public health?

municipal water supply, and, in a general way, the sanitary conditions bearing on the supply. Are there any potential sources of pollution? What is being done to safeguard the supply? Are there numerous shallow wells in use?

What is the quality of the milk supply? Are the sources of production under adequate supervision? Is the sup-

ply effectively pasteurized? Are his baby patients getting safe milk?

Is the disposal of human excreta safe? If there is a sewerage system, what disposal is made of the crude sewage? If there are many outdoor privies, are they of the sanitary type?

Is malaria prevalent in the community? If so, has any organized attempt been made to enlist state aid in a campaign for its control? Does the public understand the relation between malaria and mosquitoes? The methods of combating mosquitoes?

Does the community enjoy a system of school medical inspection? The services of a public health nurse? Is provision made for the health supervision of infants and young children?

If the community is an industrial one, the physician should familiarize himself with the important field of industrial hygiene. He should be in a position to point out the intimate relation between the sanitary conditions prevailing in the industry and the health of the community. Are the factory buildings clean, light, and adequately ventilated? Have the various special health hazards and the ordinary machinery hazards been guarded against? Is there undue industrial fatigue? What are the hours of work? Are the workers adequately nourished? Are their housing and general home environment sanitary?

Are venereal infections prevalent in the community? If so, has any attempt been made to organize the community for their control?

Is the health officer sufficiently compensated? Has he adequate assistance and proper facilities for good administrative work?

MODERN MEDICINE AS A GAUGE OF CIVILIZATION

BY W. C. BRAISTED, SURGEON GENERAL, U. S. NAVY, WASHINGTON, D. C.

THE development of medicine has always paralleled the general progress of a people and often gone ahead of it. From the remote past physicians, who in the main have been men of learning, often contributed to civilization more by their collateral knowledge than by proficiency in their own domain. Thus de Lignamine, physician to Sixtus IV, gave a powerful impulse to the new-born art of printing by setting up a press in his own home, editing the classics and serving as adviser to the publisher Hahn of Ingolstadt; Ludovico Lilio furnished the astronomical basis for the Gregorian calendar; Fracastor was a pioneer in geology and Thomas Young paved the way for deciphering the Rosetta Stone.

To-day the range of human knowledge has so increased that specialization is indispensable even within the several liberal professions, and a physician's contributions to civilization must be largely by activities within his own sphere. In thinking of modern medicine then we may well ask ourselves, What is civilization and what is the doctor's legitimate sphere?

It has been said that a country's consumption of sulphuric acid is a fair gauge of its civilization in view of the wide employment of this chemical in the industrial arts. This is not true, since industrial activity is compatible with very defective civilization. Again, it has been said that the school population is an index of civilization, but it is not the number of buildings and their equipment, nor the number of children instructed that really count. The significant thing is what the children actually learn; the permanence and accuracy of their acquirements and the bearing of the latter on their usefulness in life.

Another view is that the development of a state is indicated by the degree of accuracy and completeness with which its vital statistics are prepared and the influence which deductions from them exert, directly or indirectly, on the life and

MEDICINE A SOCIAL SCIENCE

Modern medicine is distinctly social. It is the medicine not of the sick considered merely as individuals, but of the sick en masse; of individuals in their relation to each other, of diseases affecting public morals, of diseases modifying the attitude of capital and labor, and the duties of citizens to state and state to citizen.

The study and treatment of the diseases of the day concern the vitality of the nation and its success through future generations.

Vital statistics afford a simple, practical illustration of service along the lines of social medicine.

serious defect is that conditions differ widely in the several states, some being wholly agrarian, sparsely settled, and with limited public funds.

Such a defense would have force if the collection of vital statistics were a matter of trifling moment, but vital statistics are a matter of great importance. Failure to appreciate their value is a sign of ignorance, of thoughtlessness, of a small and narrow conception of the duty of the individual and the duty of the state. Unwillingness to contribute to the collection and utilization of such data shows in the individual an indifference to his civic obligations and in the government a supineness, a weakness far from the ideals of true civilization. So far as medicine is concerned, vital statistics are collected, interpreted and acted upon with a view to the prevention and reduction of disease, but the facts deduced from them bear in many ways on the law and social institutions. Wise sanitary regulations and state and national enactments relating to health depend on accurately observed, recorded, classified facts, regarding the incidence of disease by locality and season, by age and sex; regarding the periodicity and frequency of epidemics, etc. Accurate and complete reports of births and deaths and marriages are also of extreme value in relation to property transfer, inheritance, citizenship, the issue of passports, military training and service.

The lack of enlightenment demonstrated by neglect of vital statistics is easily corrected. It is possible in a five minutes conversation to convince

welfare of the people.

It has long been a matter of reproach to our country that it lagged so far behind other nations in this particular, and today we have to confess with shame that the registration area from which reliable statistics are procurable as a basis for public health enterprises of far-reaching character includes but 77 per cent of the population of the United States. The excuse offered for this

a doctor of the importance of this subject, but to get the busy practitioner, interested in patients and fees, to make the necessary returns is another matter and there is a big difference between securing the enactment of a legal provision for health and insuring its uniform observance. The lack of civilization shows in the *unchallenged repudiation of responsibility*. Mere intellectual appreciation of the merits of a question has little value unless there is willingness to contribute time and labor to the development of the purpose involved. One is culture, the other morality.

Now, most practitioners despise clerical duties, and those who conscientiously engage therein do not enjoy them any more than those who neglect this feature of their work. It is a mistake to fancy that literary proclivities or scholarship lessen the tedium of making out forms and that only the practical surgeon, aurist or bacteriologist feels the drudgery of clerical work. The young and ambitious physician is peculiarly prone to resent the necessity of preparing returns of births and deaths and reporting cases because he does not appreciate that it is as much his duty to record his work well as it is to do good work. In one case a little benefit is individually wrought for the many, in the other a great deal is accomplished for a limited number of individuals.

Very few of us enjoy making a urinalysis and certain digital examinations are distinctly distasteful, but the satisfaction of a correct diagnosis and the glory of a cure depend on exhausting every means for securing all necessary information on a case. Anything less is not scientific, high grade medicine. As a nation we must hasten the time when our knowledge of the nation's health will be derived from a registration area representing not 77 but 100 per cent of the population. Whatever may be a doctor's individual talent in ministering to individuals he cannot be considered an all-around man, a fully functioning organ of the profession to which he belongs or of the body politic, unless he discharges his obligations to the country as a whole. If our practising physicians cannot furnish full reliable data to those who tabulate, interpret and apply them for the general good, we fall short of being in the aggregate a scientific body of men. There is no question of our ability in this respect. Have we then the will to perform our modicum of drudgery, in order that the experience, the effort, the success of all may be fully utilized for the good of all?

A state where this obtains is unquestionably highly civilized, and unless public servants are animated by this spirit they will never attain the full measure of success to which they are entitled by their opportunities and qualifications.

I have spoken at length of vital statistics because they afford a simple, practical illustration of service along the lines of social medicine. Modern medicine is distinctly social. It is the medicine not of the sick considered merely as individuals but of the sick *en masse*; of individuals in their relation to each other, as in the case of contagious diseases, of diseases affecting public morals, of diseases modifying the attitude of capital and labor and the duties of citizen to state and state to citizen. The study and treatment of the diseases of to-day concern the vitality of the nation and its success through future generations. The physician, for example, who can treat a case of hookworm or malaria and be unconscious of the social aspect of these infections and indifferent to their far-reaching effect in deteriorating the stamina of whole sections of the population has not oriented himself in the newer field of thought and action open to our brotherhood.

HEALTH AND THE JUNIOR RED CROSS

The Junior Red Cross, which was of great assistance during the war in the successful carrying on of all war winning activities, has found a definite and important peace work. The purpose of the Junior Red Cross has steadfastly been educational and, striking at the fundamental of success in life, it now aims to promote a thorough physical education among the children of our nation. In cooperation with tuberculosis associations, it has launched a Modern Health Crusade. Under the attractive conception of being pages, squires and knights warring against the Dragon Disease, just as Crusaders of old fought the Saracen host, our children are enthusiastically gaining healthful habits.

To be a Health Crusader, the child must wash his hands before each meal, his neck and ears daily, drink plenty of water, brush his teeth morning and evening, play outdoors, sleep ten hours a night, bathe several times a week, and keep neat and cheerful. As an incentive to the children, there are badges and pins of different rank awarded them after so many weeks of performing their health chores, and there are pennants for state and national winners in the tournament.

As an important issue of the Health Crusade, courses in First Aid and Home Nursing are being established in our high schools. The desperate need of instruction in these subjects was evident in the recent epidemic, when many lost lives might *not* have been lost had there been some person in the home intelligently informed on how to care for the sick. The Junior Red Cross is seeing to it that the coming generation will be fitted to cope with such a situation. More than that, it is minimizing the possibility of another epidemic. It purposes to raise the health standard of every child and to promote a better, more thorough education on a 100 per cent health basis, so that, after a few years of this régime among the youth of our nation, an epidemic will meet with a resistance which germs cannot conquer. We have every reason to expect that with parents, teachers and children cooperating in the Health Crusade this modern tournament will be the cornerstone in the new national framework of health and sane living.

A COMMUNITY SELF-ORGANIZED FOR PREVENTIVE HEALTH WORK

BY COURtenay DINWIDDIE, EXECUTIVE, OCCUPATIONAL COUNCIL, THE NATIONAL SOCIAL UNIT ORGANIZATION, AND A. G. KREIDLER, M.D., EXECUTIVE, MOHAWK-BRIGHTON PHYSICIANS COUNCIL, CINCINNATI, OHIO.

IN one of the neighborhoods of the city of Cincinnati, on the upper edge of its basin area and at the foot of one of its numerous and picturesque hills, is a community of 15,000 souls, known as the Mohawk-Brighton district. In this community is being tried out an experiment in medical administration and preventive health work which is unique. Thirty-six physicians of this district have organized themselves as a neighborhood physicians' group, not only to look after the preventive medical work of their own territory, but to work definitely with advisory groups of physicians in the city and in the nation to find the answers to some of the pressing health questions of the day. Some of the questions upon which they hope light will be thrown by this community experiment are the following:

How far is it possible, through organization of preventive health work by the physicians of a neighborhood functioning as a sort of local health board in association with other neighborhood groups to bring preventive medicine and nursing so intimately and closely into the daily life of the people as to approximate 100 per cent preventive measures?

In what way can we secure the advantages of organized medicine, of medical consultation and group diagnosis for the average physician and the average patient and at the same time preserve for the patient that exercise of personal choice in the selection of a physician which seems desirable and also avoid undesirable restrictions upon initiative and original work in the practice of medicine?

By what means may the work of public and private health agencies, the health department, public hospitals and dispensaries be coordinated most effectively, not only with one another, but with the work of the practising physician?

How may the physician work most closely with

Is it possible to enroll neighborhood physicians in a community service corps to bring preventive medicine to 100 per cent of the people?

To what extent can a community health program be made effective through neighborhood organization?

How may a real working relationship be developed among physicians, wage earners, employers, nurses, social workers, and educators?

The Social Unit, an Experiment in Applied Democracy, carried on in Cincinnati, Ohio, has ventured first into the field of preventive medicine, and the first year's experience is here detailed.

other groups in the community, such as wage earners, employers, nurses, statisticians, social workers and educators, in reaching and dealing with such underlying causes of diseases, as maladjustment in employment, unemployment, ignorance and poverty?

The physicians, through their elected medical director, are represented on a neighborhood occupational council. This council in-

cludes also the elected representatives of other neighborhood groups, such as nurses, social workers, business men, wage earners, teachers, clergymen and also recreational and publicity organizers. This is a neighborhood planning body which also is in charge of skilled services determined upon by the community. Coordinate with this occupational council, is a citizens' council, consisting of the elective representatives of each of the 31 blocks of the district containing approximately 500 people each.

While the experiment is in charge of the people of the Mohawk-Brighton District, the councils conducting the work are closely in touch with similar councils in the city and in the nation, which are acting in an advisory capacity. Thus this plan of neighborhood work is being studied and guided so that the best advice may be secured and as few mistakes as possible may be made.

Neighborhood Health Activities in 1918

Following the social unit plan of procedure, the medical work, which was the first concern of the new neighborhood organization, has been under the charge of the physicians of the district, organized as a medical group and appointing their own councils and staffs, and working with advisory councils appointed by the Academy of Medicine at their request. The nursing work has been similarly under the charge of the nurses working in the district, who, as the work has developed, have come to be the members of a neigh-

borhood staff, working with an advisory city nursing council, elected by the Graduate Nurses Association.

Baby Service.—The first service decided upon by the Mohawk-Brighton citizens' and occupational councils was for the postnatal care of babies, which was opened on December 17, 1917. The type of service in examining babies to prevent illness, instructions to their mothers, in referring them to their family physicians where treatment was necessary, and in following them up through visits to the health station and visits by the nurses to the homes, was not essentially different from that in other infant welfare centers. This service, however, was differentiated from others by several unusual features.

1. The necessity for such a service and its importance to the neighborhood were determined not by some outside agency or department which did not have contact with the neighborhood. They were determined through discussion by the block representatives with their neighbors and by the physicians, nurses and other groups and through an official vote of the citizens' and occupational councils.

2. The work of discovering the babies and of interesting the mothers in bringing them to the health station was conducted not by outside workers, but by the residents of the blocks themselves who had voted for this neighborhood service. In this way, it was distinctly a neighborhood affair in which there was no line between rich and poor. It was a matter of pride rather than otherwise to have one's baby examined by the station physicians.

3. The actual medical examination of the babies was conducted by the physicians living or practising in the neighborhood. As a consequence, they were favorable rather than antagonistic, and such benefits as come from clinical experience, consultation, and study accrued to the whole medical group rather than to some expert brought into the district.

4. As a backing for this service, not only was there a discussion prior to the decision to establish it, but also there was a careful explanation by the physicians themselves to the block workers and to other groups, such as social workers, clergymen, and teachers, of the importance of infant welfare work, its effect upon the health of the community, the methods of carrying it on, and the cooperation necessary on the part of the residents of the community itself. There was a general dissemination of this knowledge and information by the block workers and the various groups throughout the neighborhood. In addition, a public open meeting was held at which the

problem of infant welfare was discussed clearly in a popular way.

As a result of these features, which are typical of this neighborhood plan of work, in four months every one of the 297 babies under one year of age was under nursing supervision, and 70 per

The Mohawk-Brighton District A community of neighbors.

cent had been given examinations by the medical staff. As babies are born, they at once come under the nursing care. Also, the baby service has been extended to include babies between one and two years of age, and at present every baby under two is under nursing supervision. Of these, 90 per cent have visited the health station and have had careful physical examinations and many are returning at regular intervals for preventive oversight by the physicians, being referred to their family doctors for curative care.

Pre-school Service.—In cooperation with the U. S. Children's Bureau "Children's Year" campaign, every child under six in the Mohawk-Brighton District was registered by the block workers within from two to ten days. This in itself was a notable achievement and made possible an immediate campaign for complete physical examination of these children instead of the simple weighing and measuring which was the aim of the national campaign. There were 1,173 such children registered, including the babies under two, mentioned above. There were 1,007 pre-school children given a complete physical examination in three and one-half months, and 1,075 had been examined by December 31, 1918. Of those found to have defects, 370, not including 410 babies under 1 year of age, are still under nursing care because they require continued supervision. The work of securing the correction of these defects had to be practically suspended during the influenza epidemic but will be one of the prime interests of the nurses during 1919. These results are in contrast with those in other places where only the weighing and measuring of the children has been attempted.

Prenatal Service.—Studies of infant mortality show that 50 per cent of baby deaths are due to prenatal causes. The establishment of a prenatal service which will reach a large percentage of expectant mothers is the most difficult and delicate undertaking in medical work. As the result of the neighborhood organization in the

The Social Unit District is a very representative community. It has its congested section, and also its avenues like this one.

social unit district, the prenatal service, which was begun on April 1, 1918, has grown steadily through the cooperation of the block workers with the nurses and through the support of the family physicians, until 52 expectant mothers were under supervision in the month of September. This represents 45 per cent of the estimated number of pregnancies past the three months period. One conference a week is held at the station, and, although an increasing number of expectant mothers are coming to the station, the majority are supervised by the nurses in their own homes, under the direction of the family physician.

Maternity Nursing Service.—This service, while not definitely provided for in the 1918 schedule of the work, has grown up because of the actual need and demand for it. Up to the present time it has been possible for the nurse to give only postpartum care. This has been given in 73 instances out of a total of 242 births. If allowance is made for hospital admission and for the number of confinements in which midwives are called, it appears that the social unit nurses have given care to over 40 per cent of the mothers who have been delivered at home by family physicians.

During 1919, it is planned to add nursing attendance during confinement to the other neighborhood services.

Tuberculosis Service.—The health program for the district and the budget for 1918 did not include a tuberculosis service. However, the Anti-Tuberculosis League, because of its desire to see the neighborhood organization effective in the campaign against tuberculosis, offered to

assign one of its nurses, who had a somewhat larger district, to work solely in the Mohawk-Brighton district. This offer was accepted and the additional nurse took one of the nursing divisions of the district, doing general nursing for all classes of patients. The other nurses of the staff, because of this relief, were able to take up tuberculosis nursing with their other activities. On May 1 the League reported 29 patients, tuberculous, or suspected cases, requiring observation, then under their care in the Mohawk-Brighton district. This number had increased to 111 up to the time of the influenza epidemic in October. By December 31, 122 additional patients had been added to this service. It is interesting to analyze the sources of these additional patients, as follows: 3 proved to have been actually under the league's care before; 5 were discharged from the army; 4 were found to have tuberculosis upon examination at the General Hospital; 6 moved into the district, 1 of these from a neighboring state; 17 had been exposed to tuberculosis through contact with patients previously known to the Anti-Tuberculosis League. These 35 patients came through the League, in addition to the 29 first reported. Besides these, 64 were discovered through the close neighborhood contacts established by the nurses, and 23 were reported by the practising physicians of the neighborhood, making a total of 122 additional patients and 151 in all. For patients not under the care of the family physicians, and unable to pay for such care, the Anti-Tuberculosis League has given medical supervision at its dispensary. Also, the League has had the social unit nurses attend its tuberculosis clinics twice a week to help in giving them a thorough grounding in nursing supervision of tuberculous patients.

Another source for the discovery of tuberculous patients is the beginning of periodic examinations for adults, since the influenza epidemic, which it is hoped will still further build up this service during the coming year.

Bedside Nursing Service.—This service was opened in March, but because of the great and increasing demands of other services, no active efforts to build it up were made. An announcement was made by letter to all physicians that the nursing staff was prepared to care for the sick and, as patients have been reported, they have been given care. Thus, without a special effort to develop this service, it has grown steadily until, in September, 84 patients were under care. This is a great increase over the average number of patients formerly cared for in this district by the Visiting Nurse Association, but the service still has many possibilities for development.

Dental Service.—With the cooperation of the Cincinnati Dental Association and the local dentists, an examination of the teeth of the school children of the Mohawk-Brighton district has been made. These children are being followed up and an effort is being made to secure the correction of the defects found, through the nurses and block workers.

The dental situation in this district is very propitious for carrying out a dental program. This district is inadequately served and the free clinics are not sufficiently near to be used by this neighborhood. There is a definite demand emanating from the physicians, the schools and the block workers for the installation of a dental service for the community. With such an additional program, it should be possible to conduct 100 per cent examinations of school children and an intensive and continuous follow up for correction, through the nurses and block workers.

So important has the dental service seemed as part of a medical program for the district, that the dentists and physicians have definitely affiliated in a single medical group for the community.

Influenza Service.—The influenza epidemic began to develop in the Mohawk-Brighton district during the first week in October. It was necessary to discontinue practically all regular services and to throw the whole weight of the nursing staff into the handling of the epidemic. The neighborhood physicians were occupied to the fullest in caring for the tremendous demands made upon them in their private practice, but made excellent use of the nursing staff. The nurses, at the suggestion of the health officer, cared for patients outside of the district whenever called upon by the Visiting Nurse Association.

As soon as the epidemic became apparent, a leaflet giving information on the prevention of the disease and on the care of those having it, was prepared promptly in consultation with the physicians' council of the district. Within twenty-four hours this was delivered in practically every home in the district. This spread necessary and important information and also was one cause of increasing the application to the unit office for help.

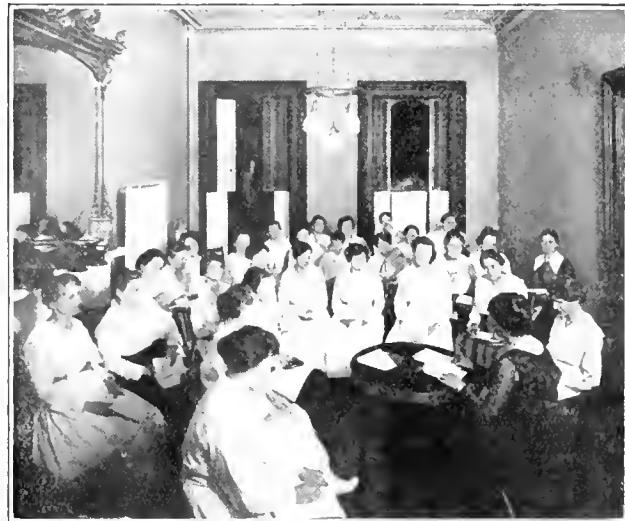

Because of the neighborhood organization and the prompt giving out of information, the demands upon the unit staff were much greater than in any other section of the city. In proportion to the population, five times as many cases of influenza were under care in the unit district as in the remainder of the city. As a result of this, better care was given. The figures show the district's death rate from influenza and resultant pneumonia to have been 2.26 per 1,000 population as compared to 4.10 per 1,000 for the

remainder of Cincinnati, and 5.79 for the remainder of the 3 wards, parts of which are embraced in the social unit area.

Periodic Examination of Adults.—The physicians' group, feeling the importance of following up convalescents from influenza in order, wherever possible, to prevent the development of tuberculosis or other diseases which result from a weakened resistance, voted for the establishment of regular conference periods for the examination of adults. These have just been begun, but already an incipient case of tuberculosis, several cases of heart lesion, chorea, and other ailments have been discovered and treatment has been instituted by the family physician or the appropriate agency.

Summary of Medical Work

The physicians in the Mohawk-Brighton district thus have done what perhaps has never been done anywhere else. They have organized themselves as a neighborhood group to look after the preventive medical work of their own territory. The excellent results secured in the examination and preventive oversight of babies and pre-school children and in other departments of the medical work would have been impossible without their active support and actual participation through rotating staffs elected by them. The physicians are paid for their services during conference periods.

Social Unit "Block Workers" who interpret skilled programs to the people of the district, and voice the people's needs and desires.

Through consultation among themselves, through conferences with city advisory committees, appointed by the Academy of Medicine at their request, through studies of literature and opinions secured from the national advisors and through the preparation of educational literature

and programs for the neighborhood, the physicians have been developing what is practically a graduate school in preventive medicine. This has reacted directly to the benefit of all coming under their observation and has proved advantageous to the physicians themselves.

In doing these things, the physicians' council has conducted the most complete known examination of children up to the school age; and has laid the foundation for a most thorough-going and intensive follow-up work of such as have defects needing correction, and also of the well, as a basis for keeping them well.

Summary of Nursing Work

The story of the nursing work in the Mohawk-Brighton district during 1918 is largely told in the description of the general health activities as already given. As in the case of the physicians, the nurses working in the district have been in charge of the nursing work and in frequent consultation with the City Advisory Nursing Council and with the National Advisory Nursing Council.

The completeness with which babies and pre-school children needing attention have been placed under nursing supervision would have been impossible except for the excellent work of the nurses in winning the confidence of the neighborhood in the exercise of wise supervision.

The statistics as to the growth of the various nursing services are striking. The baby service grew to a point where all babies are receiving nursing supervision, an increase of 1,200 per cent in a space of four months. The tuberculosis service showed an increase of 400 per cent in four months from its beginning. Bedside nursing, without an especial effort to build it up, increased to the point where five times as much of this type of work is being done in the district as in the entire city in proportion to the population. Nursing supervision of expectant mothers grew in the space of five months to a point where 45 per cent of pregnancies past the three months period were under nursing supervision. The nursing supervision of children under the school age was built up in four months so that 100 per cent of these children having defects which needed to be followed up were under care. The results achieved in establishing so effective a supervision of children under the school age and of expectant mothers appears to be unparalleled.

It is interesting to note that all of these results of nursing work were accomplished by a force averaging only twice as many in proportion to the population as the public health nursing force for the entire city (exclusive of school nurses in each case).

Instead of there being a number of nurses from different organizations visiting throughout the district, each nurse is in charge of a particular division of the territory in which she is building up toward a 100 per cent contact with all whom she can serve. There are 172 houses in the Mohawk-Brighton District in which there is more than one nursing service being performed by a single nurse and, in some cases, there are four or five services needed in the same household. The generalized plan of nursing has thus resulted in the elimination of duplication in all of these instances. Fully 75 per cent of the time spent by the average public health nurse in traveling from family to family is eliminated by this more intensive handling of services in a smaller district.

Waiting at the health station. Crowds of babies are present at every conference; 90 per cent of all children under six have been given a medical examination and are under nursing care.

All of these results were reached in the space of a few months prior to the beginning of the influenza epidemic. In three months, 756 influenza patients (not including 139 outside the district, handled as an emergency) were given nursing care. From 23 babies taken care of in December, 1917, the nursing supervision was thus extended until in August, 1918, it reached 967 patients, and during the entire year, 2,021, or about one in seven of the total population, exclusive of school children.

Work of Other Councils

Too much emphasis cannot be placed upon the impossibility of having built up so complete a health supervision without the citizens' council which is made up of the elected representatives from the 31 blocks in the district. Only a bare reference can be made to this unique neighborhood group which has been the most important element in the fundamental democracy of this plan for community organization for the purpose of com-

munity service. It is discussed more fully in literature issued by the social unit organization, which describes the part of this council of citizens in the whole plan of the unit experiment, also the census they have taken of the residents of the community, with special studies of the foreign born and the aged, and other features of their work of equal importance.

The social workers' council includes all the social workers in direct charge of social service in the neighborhood. Through this council and its frequent meetings, cooperation and harmony are assured in working out the best plans for the assistance of those in need of help in the district. From the point of view of the health worker, perhaps the most interesting development from the work of this council has been the demonstration that it is entirely feasible through a district organization of actual field workers to secure not only complete, but also continuous and intimate harmony in plans and efforts between social workers, nurses, and physicians.

A complete health program is impossible without attention to housing, recreation, and other matters recognized today as so essential to the normal healthful life. Space will not permit a discussion of these subjects and the cooperative efforts of the other councils of the community, such as the clergymen, teachers, wage earners and business men, in meeting these common problems.

That this experiment in preventive medicine and health administration is at least beginning to bring answers to some of the important health questions of the day is indicated by the interest of the members of the National Medical Council, headed by Doctor Franklin Martin, chairman of the medical division of the Council of National Defense, who makes the following comment:

"It is thoroughly sound and democratic, and will probably be used as a model in the reconstruction of medical practice after the war, or at least some modification of it."

Miss Ella Phillips Crandall, head of the National Organization for Public Health Nursing, is another of the national advisors who is helping this medical experiment through study, criticism and discussion. She says:

"I have held conferences with block workers and the executives of councils and staff workers of the social unit, and these have crystallized into a conviction my previous belief that the principles on which the social unit is built are fundamentally sound and practical. I am proud to have a part in helping it and to have had even a remote share in its work. I believe it is a living ready-to-hand expression of President Wilson's hope for community councils.

"I think that the results of the first year's (nursing) work are simply phenomenal."

Dr. René Sand, head of a Belgian mission sent to the United States, stated on a recent visit:

"The social unit plan of community organization, which is being tried out in Cincinnati, offers the most valuable suggestions for reconstruction work in Belgium which I have seen in America.

"I shall carry back to my people no more constructive suggestions than those which I have gotten from the 'social unit.'

This brief description of the health work in the Mohawk-Brighton district does not attempt fully to cover what has been accomplished by the community organization there during the past year. It gives but a partial picture of the plan of organization, as well as of but one phase of the work done. Plans for future community activities, such as the carrying out of housing standards by mutual agreement of landlords and tenants, the development of a thorough-going neighborhood program of recreation, the building up of the effective community bulletin into a real community newspaper, and many other things could be only referred to at the most.

It is hoped that no one will receive the impression that those active in the social unit experiment feel that it has found a solution for all of the pressing problems of the day. However, it is hoped that the spirit of altruism and community service, which has prevailed in the discussion of all phases of the work, is typical of the way in which the various groups will discuss even more fundamental questions of community organization and of social policy as they arise. If this is true, much may be hoped for from this form of organization, which brings all groups together, with the citizens of the community, jointly to study and to solve their social problems.

"Within certain limitations a people can have such hygienic conditions as they choose to buy. In other words, 'hygienic conditions' are purchasable, and they are safe-paying investments. No state government should delay making such investments on account of the cost. It is now well known from many demonstrations that even under the worst conditions a reasonable expenditure of public funds will afford such protection against disease as to pay large dividends, not only in the saving in human life and suffering, but also in dollars and cents.—B. S. Warren, Asst. Surgeon Gen. U. S. P. H. S.

The *American Journal of Care for Cripples*, edited by Douglas C. McMurtrie, which is the only special periodical in English on provision for the disabled, became a monthly with its January issue. Although dealing extensively with the rehabilitation of the invalided soldier, the Journal is in no sense a war product, as it is now entering upon its eighth volume. The Journal also continues as the official organ of the Federation of Associations for Cripples.

LIABILITY OF SURGEON FOR OPERATING WITHOUT PATIENT'S CONSENT

LESLIE CHILDS, ATTORNEY AT LAW, INDIANAPOLIS, IND.*

THE liability of a surgeon for operating without the consent of the patient is a question that has been rarely presented to the courts of last resort. Until quite recently there was but one such case reported in the English reports, and the American records ran them a close second.

But it is a question that is likely to be summarily brought to the attention of any surgeon at any time. Assume him to be in the operating room, the patient before him under the influence of the anesthetic, the operation perhaps commenced, when he discovers that the patient really requires another and quite different operation than the one consented to.

The question will then be, what shall he do? Shall he go ahead and operate in accordance with the newly discovered conditions? The probabilities are he will. In which event it will be interesting to know something of his liability, in case the patient afterwards discovers that fact, and possibly chooses to pin a law suit upon it.

The situation is not an impossible one, as the following case will prove. In *Mohr vs. Williams*, 95 Minn. 261, the defendant was a physician and surgeon of standing and character, specializing in disorders of the ear, and having an extensive practice. The plaintiff consulted the defendant concerning a difficulty with her right ear. The defendant examined the organ and advised that an operation be performed. At the same time he examined plaintiff's left ear but owing to the presence of a certain substance he did not make any diagnosis of the organ, and did not advise any specific treatment of the same.

Plaintiff consented to the operation being performed upon her right ear and the necessary arrangements were made. After placing plaintiff under the influence of anesthetics the defendant discovered that her left ear was in a more serious condition and in greater need of an operation.

He called the attention of plaintiff's family physician, who was present but taking no part in the operation, to the condition of the left ear. Thereupon the defendant decided to operate upon the left ear instead of the right, and the family physician making no objection, the operation was proceeded with.

The defendant performed the operation of osseiculectomy, removing a portion of the drum membrane and scraping away the diseased portion of the inner wall of the ear.

Afterwards the plaintiff brought an action to recover damages for an assault and battery. The plaintiff claimed that her hearing had been greatly impaired by the operation; that she had not previously experienced any difficulty with her left ear, and had not been informed, prior to the time she was placed under the influence of anesthetics, that any difficulty existed with reference to it; that she did not consent to the operation on her left ear, and that the action of the defendant was wrongful, unlawful, and constituted an assault and battery.

The defendant replied that there was an implied consent given; that it was a case of emergency such as to authorize the operation without the express consent of the patient. And further that there was evidence of implied consent in the fact that plaintiff's family physician was present and did not object to the operation as performed.

The lower court gave the plaintiff a judgment for \$14,322.50; however, a new trial was ordered on the grounds of it being excessive damages. An appeal was taken to the supreme court.

In passing on the case the supreme court said: "If the physician advises his patient to submit to a particular operation, and the patient weighs the dangers and risks incident to its performance, and finally consents, he thereby, in effect, enters into a contract authorizing his physician to operate to the extent of the consent given, but no further."

The court held: that the defendant had no authority to perform the operation without the plaintiff's consent, either expressed or implied; that consent was not expressly given and whether or not it was impliedly given was a question for the jury; that if neither kind of consent was given the operation constituted, in law, an assault and battery.

The proposition that the presence, and apparent acquiescence, of the plaintiff's family physician would tend to relieve the defendant of liability was disposed of by pointing out that the family physician took no active part in the operation; in fact, was there by request of the plaintiff more to allay her fears and give her more confidence. In effect holding that he had no authority, in this case, to consent to the operation as performed for the plaintiff.

*The first of a series of articles on "Law for the Doctor," written by Leslie Childs.

MEDICINE AND INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., Editor

THE NEW ERA AND MODERN MEDICINE

WE have to thank the war for the great upheaval in our public thinking. Our social fabric has been rent. The air is full of social experiments. Never was there greater need for sane, constructive thought and action.

In the new social order it is to be hoped that the medical profession will not be found wanting, but will take its proper place and assume leadership in action looking toward the better day. To qualify, however, in these world movements, the profession must first take an inventory of itself and see whether its time-honored relationships measure up to the changed social condition, whether its organization, its methods of practice, its teachings, have kept pace with the new and greater needs for public health supervision, and the industrial development of the communities.

Is the profession as a whole actually coping adequately with disease and its attendant poverty, or are its old concepts breaking down before the task? If the latter is true, what social remedies has it to propose? The profession must either assume leadership in new medical organization and legislation, or it will have foisted upon it all sorts of quack legislation, devised by unmedical minds, that will not only *not* secure to the public the predicted improvement of community and personal health, but will still further lower the economic and social status of the physician. The profession is already carrying too great a part of the public's social obligation to the unfortunates of this world.

Conference and intelligent discussion of the future of medicine, a method of securing adequate medical service and health supervision for 100 per cent of the population along with proper financial returns for such service, is imperative. In self-protection, as well as to dignify his profession, every physician must become less of an individual and think more in terms of the mass and its problems as they relate themselves to medicine. This changed attitude will come more readily to those who have been in the service.

The profession must realize that the mobilization of man power for industrial and commercial life actually lies within itself; that we have had relatively too much science and research with too little organized application of our science to the great mass of the people upon whose health and productivity finally depends the wealth of the nation. We must learn to analyze carefully the modern preventive and curative needs of the community, and then fit our medical organization to these several functions, to the end that each medical man's minimum effort will produce the maximum desired result for improved health.

Upon the medical college, particularly, falls the obligation to keep abreast of the social needs and so to train men that the graduates may be truly useful to society as a whole. This means that its faculty members must not only modernize its course of teaching for undergraduates, but must make hospital and clinical teaching available to the practising profession so as to raise the general standards of practice. Diagnostic facilities, laboratory and otherwise, must be democratized; for the day is past when the favored few shall possess these advantages at the expense of the mass of the profession and the public.

These are but a few of the reflections that come to any physician in public health work, or to one who associates himself with industry and thus comes in contact with mass problems. Fortunately for industry, more fortunately for the industrial worker, happily for society and the profession, industrial medicine has taken a strong grip on the imaginations of all socially minded men. Social workers, economists, and constructive thinking minds see in this new specialty the answer to some vexing medico-social problems.

It is because MODERN MEDICINE promises to be an open forum for the frank discussion of the economic and social values in medicine that it deserves the encouragement of all forward-looking physicians. It is because of this hope that the editorship of this section was undertaken.

EDITOR.

MODERN INDUSTRIAL MEDICINE

BY C. D. SELBY, CONSULTING HYGIENIST U. S. PUBLIC HEALTH SERVICE, TOLEDO

IN Cincinnati, the evening of February 8, there occurred a most unusual development in the progress of modern industrial medicine. The faculty of the Medical Department, University of Cincinnati, wished to establish a course of training for physicians who desire to qualify for industrial service. Funds were not available. The desirability of the course and the financial requirements for conducting it were presented to representatives of the manufacturing interests of the city with the result that a committee of employers was appointed with instructions to procure the necessary funds. The meeting at which this action occurred was marked with enthusiasm, and the speed with which those employers decided to support the medical school in the training of doctors for industrial service was a convincing testimonial of their appreciation of medical service in industry.

If the action of the Cincinnati manufacturers is a criterion of the attitude of employers generally, it is indeed a gratifying indication to the physicians in industry of the success of their efforts and of the approaching realization of their ideals. To the medical profession, however, and to the faculties of the medical colleges particularly, there is in this action the suggestion of a warning, and that warning is this, that industry is well aware of the fact that ordinary medical training and experience do not necessarily qualify for industrial service.

Medical colleges should heed this warning and should supply opportunities for undergraduates to secure training that will enable them to apply their knowledge of the theory and practice of medicine to the needs of industrial workers.

Physicians should also heed this warning and, when desiring to enter industrial service, should qualify themselves in modern industrial medicine, which is now recognized as an important branch in the science of industrial management and a well defined specialty in the theory and practice of medicine.

Modern industrial medicine is a specialty of medicine. It is also a branch in the science of industrial management, and the usual medical training does not necessarily qualify a physician for practice in the industries.

The treatment of injuries is the most evident though by no means the most important reason for industrial medical service. The physical examination is basic to the maintenance of health. It should be thoroughly made, and findings should be followed up with frequent advice and observations so that employees may be instructed how to live and labor without impairment to health.

Every physician who has added something to the knowledge of industrial medicine should make that knowledge known.

During the first six months of 1918, the U. S. Public Health Service made a study of the medical and surgical care of industrial workers and, in September, detailed to the Working Conditions Service, of the U. S. Department of Labor, the personnel necessary for its Division of Industrial Hygiene and Medicine. This division immediately became a leading agency for the development of industrial medicine and, consequently, a

center of information concerning the medical service of industry. Certain conclusions resulted from observations made during the course of the study and were verified, or modified by experience in connection with the developmental work of the Division of Industrial Hygiene and Medicine.

These conclusions have been made the basis of a program of activities which may be said to constitute the program of modern industrial medicine—a program that industry expects physicians to be familiar with and competent to carry out.

Preservation of the health of workers and the treatment of the injuries workers sustain through employment are humane measures. They are likewise industrial obligations to society. Even so, the most satisfying results to employers from industrial medical service are the reductions made in the loss of time and the loss of efficiency from conditions that impair the functioning of the human body in its relation to work. It is toward these ends that the physicians of industry must direct their greatest efforts, as it is their accomplishments in these directions that give them standing and fix their value.

In seeking to gain these results, it is essential that industrial physicians (1) assist and advise in the selection and assignment of workers, (2) supervise working conditions in so far as they affect health, (3) aid the workers in the maintenance of their health and assist them to recovery when sick and injured, (4) cooperate for the betterment of home and community conditions, and (5) endeavor to enhance the knowledge of in-

dustrial hygiene and medicine. It may be emphasized at this point that industrial physicians should very wisely not allow the urgency of surgical care to detract from the importance of thoughtful attention to the related hygienic functions of medical service.

Selection and Assignment of Workers

The measures necessary for physicians to assist and advise competently in the selection and assignment of workers are discussed under four headings as follows:

1. *Standardization of Job Requirements.*—At present the greatest difficulties physicians have in the placing of employees are (a) the lack of standards concerning maximum effort, average continued continued effort and other conditions under which women and handicapped and even normal workers may labor effectively and without danger to health, and (b) the lack of standards of the requirements of machine operations, process work and all occupations common to the establishments. Investigations are being conducted to ascertain and fix such standards, but, obviously, time will be required for their completion. In the meantime, it is suggested that industrial physicians study and classify all of the operations used in their plants, indicating their physical and temperamental requirements to the end that they may advise more effectively in the assignment of the workers.

2. *Physical Examination of Workers.*—The purpose of the physical examination is to obtain information that will enable physicians (a) to assist in the placement and replacement of workers and (b) subsequently to assist and advise both employer and workers in the maintenance of the workers' health, the former in order that he will not cause the workers to labor under conditions that may be unfavorable to their health, and the latter in order that they may live as well as labor without impairment of health.

The physical examination is basic not only to the proper assignment of employees, but also to the maintenance of their health, for without the knowledge gained through the examination no physician can intelligently advise either the employer, or his employees. In view of this, it is suggested that physicians examine workers (a) prior to employment and re-employment if the periods of absence warrant; (b) upon transfer; (c) upon termination of employment if they have been engaged in process, or other hazardous work; (d) after absence due to serious sickness, or injury not under observation; (e) when they do not feel well, or appear sick; (f) upon continued failure to measure up to the standards of

production, unless the reason is evidently not physical; (g) when engaged in process, or other hazardous work (monthly, or more frequently if necessary); (h) when handling food supplies (sufficiently often to safeguard against communicable diseases); and (i) when pathological conditions have been found (sufficiently often to guard against further impairment).

3. *Vocational Placement of Workers.*—During the war the physical examination of applicants for employment was discontinued in some establishments because the only evident result was the rejection of the unfit, a result that employers were not particularly interested in obtaining at that time when labor was scarce. To examine only is not sufficient. The findings must be analyzed—this applies to normal as well as handicapped workers—and, through cooperation with employment departments and foremen, must be used in the assignment of the workers.

The Right Man in the Right Place

Applicants are usually hired for certain operations. For illustration, let it be assumed that a man has been hired as a molder in a foundry. The physician should know what will be exacted of that man and, having examined him, must be able to say with certainty whether or not the man is physically and temperamentally qualified to do that work without impairing his health and with average physical efficiency. If the doctor finds the man unqualified; that, for instance, he has insufficient musculature to handle core boxes and castings, then the doctor should be able to suggest the work he is capable of doing. To do this in a manner satisfactory to all persons concerned, physicians must, as already indicated, have intimate knowledge of the various operations used in the plants, skill in interpreting physical values as revealed by the examinations and a close co-operation with employing offices and foremen.

4. *Instructions of New and Transferred Workers.*—Sometimes special instruction is necessary in order that workers may adapt themselves to their jobs and safeguard themselves against hazards that cannot wholly be avoided. This applies, for example, to workers in lead, TNT, and other poisons, also to female and handicapped workers under certain conditions. Physicians may reasonably be expected to offer instruction of this nature at the time of examination, which is an opportune time, and to do so they must be (a) familiar with the hazards of their plants, (b) prepared to instruct employees when necessary, and (c) supplied with pamphlets for distribution among those employees selected for the hazardous jobs.

Hygienic Supervision of Working Conditions

Because of their knowledge of the human body, physicians may be expected, when they assume industrial service, also to have knowledge of all working conditions in their relations to the health of the workers. They may be expected further to exercise such supervision over working conditions as is necessary to protect the workers from unhealthy conditions. The measures essential to supervision of this character are discussed under three headings as follows:

1. *Inspections.*—Obviously physicians cannot supervise working conditions, unless they have intimate knowledge of the conditions existing in their plants. For the procurement of this information it is suggested that they, or their assistants, make periodical tours of the establishments. Conditions specially to be sought and studied are: (a) monotony, (b) concentration, (c) isolation, (d) speed, (e) overtime, (f) inadequate ventilation, (g) poor illumination, (h) excessive variations in temperature, (i) excessive variations in humidity, (j) harmful dusts, (k) gases and fumes, (l) poisons, (m) inadequate sewage and waste disposal, (n) inadequate toilet, washing and locker facilities, (o) unsafe drinking water, (p) workroom congestion, (q) poorly adapted workroom clothing, (r) unnecessary noises, (s) lack of mechanical safeguards (if safety service is not otherwise provided for), and (t) workroom disorder.

2. *Investigations.*—Certain processes, operations, and methods required by industry are known to be harmful to health; others are suspected of being so. While investigations have been made and conclusions have been reached in regard to many health hazards, there are yet great opportunities for the enrichment of knowledge in this direction. It is devoutly to be hoped that industrial physicians will accept their many opportunities to study particularly those hazards that are not well understood and to determine means for their prevention.

This Factory Needed Physician's Service

A Cincinnati manufacturer recently remarked that a process he was forced to introduce in his plant in order to supply certain materials for war purposes resulted in sickness among the workers. He sought the advice of physicians for the cure and prevention of this sickness without appreciable success. This is one of a number of illustrations that may be cited as an indication of the opportunities awaiting the physicians of industry and, incidentally, the paucity of general interest in the researches necessary to make industry safe for the workers.

3. *Instruction of Foremen and Management.*—

While production is paramount in industry, employers certainly do not wish to jeopardize unnecessarily the health of the workers. If working conditions are such that harmful effects do or may result, the assumption is that the employers are not aware of them, nor informed on means for their correction. These matters are left very properly to physicians and sanitarians, and the initiative in the correction of unfavorable conditions must necessarily rest with them. It is suggested, therefore, that industrial physicians take special pains to inform employers and foremen tactfully but clearly of (a) the existence of unhealthy conditions, (b) their harmful effects and (c) means for their correction.

Health Maintenance

While it is true that unfavorable working conditions are capable of impairing the health of workers, they are not alone responsible for impaired health. Much depends upon the workers themselves and the manner in which they live and sustain themselves. Although the workers are free agents and privileged to live and sustain themselves as they see fit, physicians are able to assist them greatly through advice and service in the maintenance of health. As an aid to efficiency and production, employers realize the advantage of extending their workers assistance of this nature, particularly in so far as relates to the maintenance of health during hours of employment, and quite naturally they look to physicians for this assistance. Activities in this connection are discussed under six headings as follows:

1. *Health Instruction.*—Unfortunately the knowledge imparted through our general system of education does not teach people the essentials of hygiene and health maintenance, and consequently workers may be expected unknowingly to violate the rules of health. In order that they may not be so handicapped, it is suggested that industrial physicians endeavor through lectures, personal talks, bulletins, posters, articles in shop papers, etc., to instruct workers in (a) personal hygiene, (b) proper clothing, (c) proper food, (d) recreation, (e) rest, (f) exercise, (g) prevention of communicable diseases, (h) personal habits, etc.

2. *Provisions and Facilities for Care of Health in the Plants.*—Instruction in the maintenance of health is not alone sufficient. Provision must be made and facilities furnished within the plants in order that workers may be induced and enabled to apply the principles of health maintenance during working hours. Although industrial physicians have manifested little interest in this direction, it

is reasonable to believe that their knowledge is such as to qualify them to advise on, if not to supervise, all activities necessary to prevent fatigue and the impairment of vitality. In applying their knowledge to this end, it is recommended that physicians direct their attentions to (a) the procurement and operation of facilities for rest, recreation and exercise, (b) the designations of workers who should have the benefits of rest, recreation or exercise, and (c) the conditions under which they should avail themselves of these benefits. It is further recommended that physicians interest themselves in (d) the procurement of refreshment facilities (restaurants and refreshment stations), (e) the supervision of restaurants, refreshment stations, kitchens and storage rooms for food, and (g) the daily inspection and monthly examination of all food handlers (for prevention of communicable diseases).

3. Prevention of Communicable Diseases.—The necessity of preventing, or at least controlling, communicable diseases among industrial workers is evident. The difficulty is in applying the measures necessary. Theoretically, it might appear that a daily inspection of all employees by physicians, or their assistants, would serve to bring communicable diseases to attention in their incipiency. However, in large establishments this is impracticable, although in times of epidemic serious efforts should be made to carry on such inspections. Under ordinary circumstances, physicians should arrange with foremen to require all employees who have the appearance of being sick, especially those who have eruptions, and those who do not feel well to report at the dispensary for diagnosis at least. It is scarcely necessary to mention in this connection that all who are found suffering with communicable diseases should be excluded and health authorities notified of all reportable cases. The rapid development of vaccines and other immunizing agents has opened up for the industrial surgeon a field prolific in opportunity for the prevention of certain communicable diseases.

4. Treatment of Trivial Illnesses.—It seems industrial workers, as well as others, are prone to neglect non-incapacitating illnesses, such as colds, headaches, constipation, etc. As these are sometimes early symptoms of more serious illness and, therefore, the forerunners of incapacity and lost time, employers have found it beneficial to the workers, as well as advantageous to production, to have all trivial ailments that become evident during working hours treated by their physicians. In the interest of efficiency and for the maintenance of health of industrial workers, it is therefore suggested that physicians encourage workers

to seek treatment for the relief of trivial illnesses, occurring during the hours of employment, which they ordinarily would neglect.

5. Prophylactic and Emergency Dental Attention.—Inasmuch as neglect of teeth, which is quite prevalent, results in a variety of infections and other disabling diseases, employers are finding it to their advantage more and more, and to the benefit of the workers, to provide prophylactic and emergency treatment of teeth. Prophylactic dental treatments are of great educational value in the maintenance of health, and the treatment of dental emergencies—toothache, etc.—arising during working hours is useful in giving relief and enabling workers to continue employment. The industrial physicians are urged to secure personnel and facilities for dental service and to encourage the workers to avail themselves of it.

6. Surgical Treatment.—The most evident reason for the existence of industrial physicians is, of course, the treatment of injuries. This is mentioned at this time to indicate the fact that the surgical treatment of injuries is a function necessary to the maintenance of health, and also to emphasize the fact that it is but one of several important functions. The importance of surgical service is determined largely by its emergency features. Measures which obviate the need of surgical treatments, and also medical treatments, would seem to be equally essential and of perhaps greater importance. Also, reconstructive surgery, which has recently come to the attention of industrial physicians, brings to them the suggestion that they can very well initiate rehabilitation measures early in the care of injured workers. Reconstruction and rehabilitation may also be applied to the benefit of workers who are handicapped because of hernia and other more or less incapacitating conditions.

Better Home and Community Conditions

Employers may be exceeding their responsibilities when they endeavor to assist workers in handling difficulties which arise in their personal affairs and when they attempt to improve community conditions, yet employers have a definite interest in these matters in so far as they cause worry and impairment of vitality among the workers.

1. Social Aid.—The position which physicians occupy in the lives of people confers upon them, to a certain degree, the responsibility of advising with them in the solution of problems that are more or less of a personal nature, as well as of interest to community life. It is suggested that physicians take advantage of this relationship (a) to advise and assist workers in

the adjustment of social and financial troubles, (b) to encourage thrift, domesticity, sobriety, morality, and (c) to offer instruction in health and sanitation. In those establishments which have sociological departments, physicians may be expected to cooperate with them in the foregoing activities.

2. *Medical Aid*.—Sometimes workers are unable to obtain for themselves and their dependents adequate medical, dental and nursing attention and, although employers may not be responsible, they realize that sickness in the families of their workers may be a source of considerable worry and, therefore, detrimental to production. Because of the knowledge which physicians have of doctors, dentists, nurses, hospitals, clinics, and nursing relief societies in their communities, it is suggested that they endeavor to assist in providing adequate medical service for the workers and for their dependents when they are unable to procure it for themselves. Actual nursing aid may be given with advantage for short periods by the visiting nurses of industrial establishments, acting under the directions of the patients' own physicians.

3. *Community Aid*.—Through their relations with workers in connection with the foregoing activities, industrial physicians frequently become aware of community conditions which are unfavorable to health. It is highly desirable that they use this information, when they can consistently do so, for the betterment of community conditions; in so doing, they should act in cooperation with national, state, and local health authorities, with other industrial establishments and particularly with the social agencies of their communities. With respect to the last mentioned, the attention of industrial physicians is drawn to the fact that employers are large contributors to charity. Any assistance that their physicians may be to those charities in which they are interested will undoubtedly be appreciated by them.

Enhancement of Knowledge

Industrial medicine is new. It is yet in its developmental stage. Only by the contributions of interested physicians can it be developed further. Every man who has added something to the knowledge of industrial hygiene and medicine owes it to industry and to medicine to make that knowledge known. It is also incumbent upon industrial physicians that they make studies of the material which they have at hand in their own establishments and endeavor to stimulate their own assistants and attendants in the pursuit of researches. Unfortunately, industrial physicians as a rule find their time taken up with routine

work and because of this they are, perhaps, unconsciously in danger of becoming restricted in their breadth of knowledge and limited in their scope of activities. To obviate this tendency, it is recommended that they hold meetings of the personnel of their own establishments, when of sufficient numbers, for the study and discussion of those matters that concern the health problems of their industries. It is also suggested that they arrange with their fellows in other establishments for conference groups for similar studies.

Opportunities of Industrial Hygiene and Medicine

No branch of medicine has come so prominently to the front in recent years as industrial medicine. Industry and the medical profession both have been surprised to discover in it wonderful opportunities for usefulness in the conservation of health and limb and through this for the promotion of industrial efficiency and the facilitation of industrial production. In view of the inestimable opportunities which industrial service offers physicians to exercise their knowledge and skill not only in the behalf of industry, but also in the behalf of the industrial workers, it is suggested that the physicians of industry bring themselves to a full realization of the dignity of their profession and the value of the service they are capable of rendering. This can be done only by their concentration of time and efforts to the service and their complete availment of the opportunities it offers for the prevention of illness, as well as for the treatment of injuries.

CINCINNATI BOOSTS INDUSTRIAL MEDICINE

A group of one hundred Cincinnati business men have pledged their support to the Cincinnati University in establishing a department in the Cincinnati University Medical School for the training of industrial physicians.

Dr. Otto P. Geier and Fred A. Geier, president of the Cincinnati Milling Machine Company, invited discussion of the plan at a meeting held recently at the company's plant. Dr. C. D. Selby of the Industrial Hygiene Division of the U. S. Public Health Service, who has just completed a survey of one hundred and fifty medical departments in industries throughout the country, pointed out the ideals of industrial medicine and explained the qualifications of industrial physicians sketched. He indicated the necessity for special training for physicians for the new type of work.

Major C. R. Holmes, dean of the Medical School, then set forth the immediate needs of the medical school if such a department were created. He suggested a guarantee fund of \$15,000 a year for five years, or a permanent endowment support to yield \$15,000 a year to be raised by subscription.

John A. Lapp, director of the Ohio Health and Old Age Insurance Commission, indicated the extent of the problem of sickness in industry by citing statistics to the effect that twenty per cent of all workers have a disabling sickness of more than one week every year.

A PROGRAM OF HEALTH AS APPLIED BY THE AMERICAN PULLEY COMPANY

BY WILLIAM ALFRED SAWYER, B.S., M.D., CHIEF OF DEPARTMENT OF HEALTH AND EMPLOYMENT, PHILADELPHIA

OUR present-day civilization is essentially an industrial one. It has long been conceded that the fitness of the factory—its machinery and other equipment—is a responsibility attaching to the employer, whose financial interests are served by its perfect adjustment, but the fitness of the employee as an industrial asset has been ignored altogether, or has been regarded as the employee's own individual problem. There is, however, a growing appreciation of the effect of physical and mental adequacy of the employed upon the returns of business and the well-being of employees is becoming one of the most cogent factors of business management today. In the consideration of the human potential, we are concerned that its functioning be adequate, whether viewed collectively or individually, a condition which cannot obtain without due regard to the laws of health and compensation, and which is naturally limited by the range of general adaptation of the individual worker.

We may safely conclude, and our study and practice will bear us out, that a workman is capable according to his possession of (1) health; (2) freedom from worry (which presupposes adequate compensation in the form of both wage and opportunity); and (3) natural and educational adaptability for the work engaged in. The more capable the worker, the greater the asset to his employer, and the wide-awake employer is coming to prefer a selection of employees upon some such basis.

1. In our analysis of health we find a limiting clause: What are we to do with the great number of individuals having ailments and disorders, inadequacies and disabilities? They must work and, if properly placed, in most instances can do so acceptably and without augmenting their limitations. Health supervision must be sympathetic as well as intelligent.

2. All problems must be considered that pertain

AXIOMS OF THE FACTORY

PHYSICIAN

We must have health among our employees; without it production cannot be kept up.

When an employer aims to keep his workmen healthy he shows sound business judgment as well as decent human interest.

In industry a physical examination is a safety first move for the company, for the men of the plant, and for the applicant.

The proper spirit engendered within the plant will spread to the home and through the surrounding community, and the plant becomes a definite social asset.

to spiritual contentment and that help to instill some bit of divine discontent, or ambition, for contentment and ambition should be inseparable. To this end the worker must be provided good surroundings, careful assignment of tasks, considerate instruction and such facilities, supervision and cooperation as will develop and maintain the greatest productiveness. The people may be considered *en masse* for one purpose

or another, but back of all collective forces is the individual, and the only way to reach the mass is to influence, appeal to, and better understand the individual. An underlying cause of much of the present-day restlessness and discontent is the lack of a proper estimation of the relationship between physical and social strain.

3. The relation between mental capacity, powers of endurance, and a consistent health program is clear. The advisability of some standardization of mental capacity and of trade tests to determine natural fitness or adaptability is not so obvious, but wherever these methods have had a fair application their efficacy has warranted the measures. The discovery of an individual's limitations protects him against the failure of a misfit. Success and contentment are promoted and the interests of all are served.

So much investigation needs to be made, so many observations are to be checked and correlated before final conclusions may be drawn, that each center of consistent endeavor to know and meet social and industrial problems should report its methods and results. The plan at the American Pulley Company (Philadelphia) has involved: preliminary physical examination, periodical physical examination, dental care, rest and recreation, dispensary service.

Preliminary Physical Examination

The physical examination which we give at the American Pulley Company to all promising ap-

plicants is in no sense so complete as that made by insurance companies or the army or navy, and, while the man we pass might be a good policy risk or fighting chance, we aim to accept only good working possibilities. For that purpose it is sufficient to detect conditions that might soon prove harmful to the man himself or to those with whom he works. We reject all cases of hernia, offering to send them for care to the best talent the city affords. Our examination eliminates a man unless he can see with both eyes, and it excludes anyone with such errors of vision that he would be unable to avoid the hazards of shop and yard. A man whose vision is subnormal is at

nothing seriously wrong. On occasions men and boys have bolted from the employment office upon discovering that a physical examination was necessary. We have even had some admit that they could not pass an examination. This perhaps explains why we have not seen many cases of venereal infection, and comparatively few other abnormal conditions. For this and other self-evident reasons the effort is worth all that it costs.

Periodical Physical Examination

Usually when old hands bring friends for a job, they say: "If he can pass the examination, he'll make a good man." They have come to re-

Room for examinations and first aid

the best not an efficient producer, and is prone to many disorders of reflex nervous origin. Usually we have offered to employ these men when they would secure proper glasses. We avoid putting a man with an impaired heart on work which might further injure it. We feel that the protection to the plant from the exclusion of contagious diseases is alone worth a great deal. In making the examination we are brought closer, through the vocal and physical responses, to the mental status of the applicant, and this is surely an important element in estimating his value to the force.

We believe that a plant which examines physically soon establishes a reputation in the community among the workers, and that only those apply for work who are reasonably sure they have

spect it, and I am sure that once adopted into the routine of hiring, it will never be abandoned.

While the healthy workman is rapidly becoming an objective of the wise employer, it is certain a workman's own health means still more to himself. We are aware, however, of the average workman's ignorance and indifference to the value of keeping physically fit. Many choose jobs for which they are constitutionally unfit, and so expose themselves to accidents or sickness; others do not know how often it is ill health that fags them out, or how largely their habits are contributing causes. Whatever the cause of poor health, or wherever the responsibility may lie, it is quite evident that any decline in health results in financial loss to both employer and employee.

When, therefore, an employer aims to keep his workmen healthy, he shows sound business judgment as well as decent human interest. At last the prudent employer is finding it a good investment and a cause for personal satisfaction to look after his employees' health by maintaining a general oversight of their physical condition, so as to detect and remedy in time those subtle, unsuspected diseases that make men "rusty" or that tend to throw them "out of gear."

Reexamination should be made at least yearly, perhaps every six months in certain types of industry. When a worker is absent rather often or for any extended length of time without ap-

ship of physical impairments to capacity for work, for constantly we are gaining more and more knowledge of the increased number of ways that incapacitated individuals can employ themselves.

In industry a physical examination is a "safety first" move for the company, for the men of the plant and for the applicant. The latter is often unaware of the defects he is harboring and usually appreciates an unprejudiced opinion. To my mind, the physical fitness of the worker should be the basis of his selection. Perhaps I view this matter only through the eyes of a physician; be that as it may, I certainly believe that a human service department must build itself on health

Wash basins are placed in surroundings that have a general aspect of cleanliness.

parent reasons, or because of evident poor health, an examination should be made to determine to what extent his working conditions may be responsible. At each reexamination a comparison should be made with the record of the previous inspections to see wherein the individual is improving or deteriorating. In each case the worker should be apprised of his condition and given complete instructions as to the best course to pursue. So often the routine tests are made with no remarks whatever to the employee, as if putting data on a record card were the sole aim of the proceedings. Each examination must be in a sense an instruction period, and all possible information should be imparted. At the time of reexamination it is possible to make studies of the relation-

work, and one of its first essentials is the selection—for the sake of industry in all it involves now and in succeeding generations—of men fit to assume the burden. That does not mean that large numbers will be ruled out; it means that men unfit for hard, laborious work will eventually be directed into safe places, and those with defects which can be corrected will virtually be forced to attend to their health before expecting the better grades of jobs. We want to save men for industry and not destroy them.

Naturally, there is always the question: Has industry a right to throw upon the community men physically imperfect? Yet, when it is recalled that probably 60 per cent of these substandard conditions are remediable, being simply the

result of ignorance and neglect, is it not time that industry should do what it can to detect and alleviate?

Dental Care at Minimum Cost

We are only beginning to scratch the surface with regard to measures to preserve normal, healthy teeth. There can be no doubt as to the wisdom of thorough dental examination with insistence and follow up, in many instances, to see that decayed conditions are corrected. Often it is possible for large plants to furnish dental work at a minimum cost, at least for work of an urgent character. It will save much time lost.

sending the man to a hospital for further care. Our men are encouraged to consult the doctor of the plant concerning any illness whatsoever of their own or of those in their families. They now come, as we want them to, with very minor ailments, and we think are beginning to be healthily interested in maintaining a good physical condition. In no place is the proverb, "An ounce of prevention is worth a pound of cure," more completely fulfilled than when applied to health. Here, to cure is a science, to preclude an art. Our work should be and must be more largely prevention of sickness, and we should offer the workingman an opportunity whereby he can consult proper author-

View of athletic grounds. Baseball game in progress.

Rest and Recreation

Every plant should make provision for rest and recreation, the periods of rest and the kind of recreation to be in accordance with a plan worked out according to the special industrial and social needs of the workers. The illustrations of this article are taken from Building No. 25 for the convenience of our workmen and for safeguarding their health, and represent the trend of our health and welfare work with regard to rest, recreation and provision against undue strain as one of the most essential features of health supervision.

Aside from the examination of a man to determine his fitness to become one of our force, we treat all usual accidents occurring in the plant, and give first aid to any of a serious nature before

ity concerning incipient illness. There is a wonderful point of approach by means of the dispensary. We all know how much more freely a man will talk with his doctor than with any other man. An industrial doctor who simply cares for those injured and makes only his regular physical examinations is not exhausting his possibilities for usefulness to the plant he serves and he cannot do so until he assumes a more vital relation to the welfare of the men. Dr. Geier of the Cincinnati Milling Machine Company has voiced my own thought along this line and crystallized it in such adequate language in his paper on "The Human Potential in Industry," that I shall quote him:

"The activities of the human service department should be founded on intensive health work. Health is our most

vital possession. The mere act of conserving the health is ennobling. Healthy bodies promote right thinking, right living, good habits, and it is upon such factors that intelligence, stability and loyalty are engendered. Unless we have these things, our employment departments, struggling with the labor turnover, our mutual benefit societies, and loan associations, our restaurants, cooperative buying, our sanitary measures, will meet with but half of the deserved success."

The proper spirit engendered within the plant will spread to the home and through the surrounding community, and the plant becomes a definite social asset.

Deprive None of Hospital Care

In looking after our men I have been very much impressed with the difficulty of securing sufficient and satisfactory care for them when ill. Despite Philadelphia's numerous hospitals, I have often found their facilities inadequate. Can you imagine the power and usefulness of a hospital in which there were no preferred classes, a hospital conducted solely for the men of our industries and their families? Such a hospital, founded upon the broadest humanitarian principles, would act also as a center for health education, and would soon become an institution of ever-increasing authority and usefulness. The fear of such places, which now so largely exists, would give way to dependence and confidence. So few of our men or of those in their families who fall ill are able to get proper care at home that with the services of such a hospital the time away from the job could often

be greatly reduced and much of the present strain upon their resources lessened. I should like to see some such plan as this, together with plant medical supervision, augment compulsory health insurance.

The sense of the responsibility of the employer to the employee will doubtless continue to increase. This responsibility would, of course, better be voluntarily assumed and should go hand in hand with cooperative effort along all lines of industrial relations. The employer will assume his part in such things as housing, transportation, supplies, education, morals and recreation. The opportunity is obvious; the responsibility will be assumed by some one and to him will go the prestige, leadership and success. To big business this opportunity is presented more profitably than ever before. In view of the physical shortcomings as brought forth by the examination of our young men for the army, does it not behoove us to about face and see wherein industry can profit by this experience? We must have health among our employees; without it, production cannot be kept up. Industry cannot make the rapid strides necessary in these momentous times. We must have these examinations upon entry to the plant, and periodic examinations at intervals of six months or a year thereafter. The social group is better for the aid to each individual unit, and everything that means Americanism in its best sense must be made possible for service and production.

ACUTE SEPTIC INFECTIONS OF THE FINGERS

BY ARRIE BAMBERGER, B.S., M.D., ASSOCIATE IN SURGERY, MEDICAL DEPARTMENT UNIVERSITY OF ILLINOIS, ATTENDING PHYSICIAN COOK COUNTY HOSPITAL, CHICAGO.

PROBABLY no surgical condition is of more importance and requires more careful treatment than do the acute infections of the fingers. To the workman a loss of function of one or more fingers often means the loss of his occupation and final pauperism. There are numerous classifications of acute infections of the fingers, many of which are ambiguous and cloud the minds of the practitioner as well as the student. The older terms—paronychia, whitlow, and felon—I believe should be discarded, as they do not designate precisely any type of finger infection. The better classification is the pathological one, naming the exact structures of the finger involved: the subcuticular infection, immediately under the epidermis or cuticle; the subcutaneous infection, involving subcutaneous tissue; the tenosynovitis, involving tendon sheaths; and osteomyelitis, involv-

ing infection of the bone. One or more of these types of infection may exist, by simple extension of the infection from one structure to the next underlying one.

Etiology.—External trauma of any description—scratches from fish scales and meat bones, and manicuring of nails in which the cuticle is cut too close to the skin—are the frequent causes of septic infections of the fingers. An adjunct cause, if we may so term it, I believe is the indiscriminate use of hydrogen peroxid after an injury; especially so if foreign material has been introduced into the wound. The first step that usually the layman takes, and indeed many physicians, in cleaning a wound of the finger is to wash that wound thoroughly with hydrogen peroxid. From the many cases of infections of the fingers which I have seen following the use of hydrogen

peroxid in the fresh wound, I feel firmly convinced that the gaseous oxygen liberated by the peroxid in the wound forces the bacteria into the healthy as well as into the injured tissues, and thus produces infection which otherwise would not have occurred.

Symptoms.—All of the types of acute septic infection of the fingers produce pain in the affected part, and more or less swelling. The subcuticular type of infection manifests itself by a bleb-like formation, which contains a serosanguinous fluid; the pain and tenderness is slight. In the subcutaneous type, which is most frequent, we find the involved area markedly swollen, red, tender, and fluctuating if pus is present; lymphangitis and neighboring lymphadenitis are frequently present, especially in the streptococcal infections and in those in which there is no free drainage. In tenosynovitis there is severe deep tenderness over the sheath of the tendon involved, and the patient does not move the finger because of the great amount of pain on the slightest movement of the tendon. In osteomyelitis of the phalanges and septic arthritis of the interphalangeal joints there is a very hard and large swelling, much greater than in any of the other types of infection. The tenderness and swelling is deep—that is, it does not involve the subcutaneous tissue alone, but involves the deeper structures. Usually, in a subcutaneous type of infection, when the swelling does not subside within seven to ten days, but remains stationary or increases, we are then dealing with a bone infection. When the osteomyelitis begins, there is a great deal of pain, which subsides after four to seven days, but the swelling persists and pus continues to drain from the wound. An x-ray picture will show the necrotic bone.

Treatment.—Prophylaxis is most important. In an injury of the finger the foreign material, if present, should be removed. The tissue adjacent to the wound, but not the wound itself, should be washed with green soap and water. The wound itself should be first lightly touched with a pledget of cotton soaked in bichlorid of mercury, solution 1:5000 dilution (no rubbing should be done), and then swabbed with tincture of iodin. A hot boric acid dressing is then applied, which should be renewed in twelve hours, and so continued until the wound shows signs of healing, when a dry dressing is applied if no infection is present.

Active Treatment.—In all types of finger infections where pus is present, incise and drain the part. The incision should be a large one and a crucial incision; the longest part of the incision is made in the longitudinal direction, while short transverse incisions are made through the skin only in order to keep the wound from closing too

rapidly. A probe is passed into the wound, so that any pockets can be located and opened up along the course of the probe. When a tenosynovitis is present, the infected sheaths are opened up and drained. When an osteomyelitis is present, after the x-ray shows the necrotic bone well demarcated, under gas anesthesia the necrotic bone is removed and the fistulous tract curetted. I do not believe in temporizing in these cases, waiting for the bone to slough off by itself. If this latter method is used, I find that more bone becomes involved, and a much longer time is consumed for the recovery of the patient. For drainage I use sterile gutta-percha tissue folded into small strips, which is much superior to the gauze drains, which become dry and stiff from the secretions of the wound, and then act as a plug in the wound rather than a drain. The gutta-percha is smooth, non-irritating, keeps the edges of the wound apart, and in no way plugs up drainage as does gauze. Hot boric dressings are used, and it is important to use enough gauze in making the dressing—not two or three layers of gauze, but ten to twenty. A window is cut in the bandage, so that hot boric acid solution can be poured into the dressing every hour, and the entire dressing is changed every twenty-four hours.

Summary.—The points to be emphasized are:

1. Hydrogen peroxid should not be used as a first-aid cleansing measure; the oxygen liberated forces infection into the tissues.
2. Early diagnosis of osteomyelitis and early excision of necrotic bone are important.
3. Large incisions are called for in all infections of the fingers.
4. The use of gutta-percha tissue as drainage material instead of gauze is advisable.

NO PHYSICIAN—NO FACTORY

The subject of industrial medicine has invaded the lay journals and it is not uncommon to find discussions of it in business periodicals, also. The health of workmen has come to have an intensive interest to employers and managers because "it pays to keep skilled employees on the job instead of hiring poor substitutes to cover periods of illness."

Dr. Ralph W. Elliott, of the National Lamp Works, Cleveland, described in *Factory*, the magazine of management, for February, the work which his company does to keep the men well. He told of the health education work, the treatment of minor ailments, the prevention of contagion, the treatment of colds, the necessity for dental examinations, provisions for first aid in case of accident, and the value of sanitary surroundings.

A significant statement is quoted, showing the approval by employers. "If I were planning," said a factory executive, "to start up a manufacturing plant today, but could not install a medical department at the start because of a lack of financial means, I wouldn't start the factory at all."

CARBON MONOXID POISONING

BY A. J. LANZA, SENIOR SURGEON, U. S. PUBLIC HEALTH SERVICE, CHIEF DIVISION OF INDUSTRIAL HYGIENE AND MEDICINE, WORKING CONDITIONS SERVICE, DEPARTMENT OF LABOR, WASHINGTON, D. C.

THREE is no subject included under the general scope of industrial poisoning or occupational illness more interesting or of greater practical importance than carbon monoxide poisoning. Not only is exposure to this gas prevalent in a great many industries, but it is intimately associated with heating and illumination of the home. Kober and Hanson mention thirty-four industries where CO poisoning may occur, and Doctor Albaugh states that there are at least thirty such industries in the state of Ohio alone. Besides being recognized as a definite hazard of various processes in many industries, CO poisoning occurs under the strangest and most unexpected circumstances. Indeed, so unusual are the circumstances of CO poisoning at times that its nature may not be recognized until a succession of fatalities reveal the true cause. It is a fruitful cause of death, from the individual who is overcome while tinkering with his automobile in a small garage to the wholesale slaughter that occurs in mine fires or explosions.

The prevention of CO poisoning depends on a proper recognition of the possible sources of the gas and the taking of precautions to prevent those necessarily exposed to it from being overcome. Caused chiefly by incomplete combustion of carbonaceous material, it is impossible to prevent the formation of this gas under a multitude of different conditions. Where there is reason to believe that carbon monoxide is being liberated into the air of a working place with more or less regularity, due to the nature of the process involved, the air of such place should be sampled and analyzed from time to time. It being established that there is a carbon monoxide content in the air, every effort should be made to remove it. Leaks in mains, conduits, pipes or other carelessness on the part of the management or of employees may be responsible, in which case the remedy is evident. In other places or processes it may be possible to remove the gas by proper hooding or exhausts, or when such form of removal is impracticable there should be free and open ventilation, with every facility for exchange of inside and outside air.

There will of necessity be many occasions where carbon monoxide cannot be prevented from polluting the air where men may work, even if only temporarily, and where also the gas cannot be readily removed. The nature and location of the

work will determine the course to be followed, but in any event carbon monoxide cannot be treated with too much respect. It may be accepted that where CO is known to be present or suspected of being so, no man should be allowed to go unattended or unwatched, even when wearing oxygen apparatus. When it becomes necessary, as in times of emergency or disaster, for men to penetrate an atmosphere containing CO, not less than six or seven men should be allowed to go in a party, even when equipped with oxygen apparatus. Under many occasions the prevention of CO poisoning will depend on the intelligence and watchfulness of the individual. The person engaged in regulating his motor car, the workman in fire or boiler rooms, the man working around blast furnaces and by-product coke ovens, the miner and many others should always remember the insidious and dangerous character of the gas to which they are exposed. Prevention lies, then, largely within the domain of "safety first."

Relative to continued exposure to CO, the effects of which are discussed later, men should not be allowed to work steadily in an atmosphere which contains even minute quantities of the gas. If the gas cannot be removed, men should be moved from time to time.

The treatment of carbon monoxide poisoning is a matter of some dispute. The actual effect of CO gas is the subject of controversy and the status of chronic CO poisoning is not clear. In 1916 Professor Yandell Henderson, holding the chair of physiology at Yale, and acting on the United States Bureau of Mines committee on resuscitation from mine gas, as a result of certain experiments and experiences, made announcements relative to the action of CO that were at variance with previously accepted theories. Briefly, Doctor Henderson concluded:

"Carbon monoxide is physiologically harmless except in its affinity for hemoglobin. Its toxic effects are wholly due to the inability of the blood combined with CO to carry oxygen to the tissues.

"Carbon monoxide does not form a permanent compound with hemoglobin, but is rapidly separated from it in the presence of pure air or oxygen.

"The continuance of coma or after effects of CO are not due to retention of gas but to the results of injury to the tissues due to the insufficiency of oxygen while the gas was being inhaled.

"Therefore," Doctor Henderson concluded further, "in CO poisoning neither transfusion nor bleeding is beneficial, oxygen inhalation is of value for a brief period only, say half an hour, and exposure to fresh air and symptomatic treatment are all that are really required."

Previous to this announcement, it was generally accepted that the combination of CO with hemoglobin was a permanent one, or at least of a very tenacious nature. Personally, as far as our experience goes, I am inclined to agree with Doctor Henderson's conclusions. While associated with the U. S. Bureau of Mines in work relating to mine hygiene it was the custom to take samples of blood from persons overcome by mine gases, whenever possible, especially if engaged in rescue work and wearing oxygen apparatus. In a series of fatal cases we found discrepancies in the CO content of the blood and never in sufficient concentration to produce death. On going into the matter further we found that the method of taking the sample had much to do with the accuracy of the analysis. At first we drew the blood into a syringe, squirted it into a small bottle, sealed it and sent it to the laboratory. We found that the aeration of the blood during its transfer from the syringe to the bottle materially lessened its CO content, and that if we did not fill the bottle full, the air remaining between the blood and the stopper displaced CO. In all handling of the sample, therefore, we had to avoid exposure to the air, which would seem to be in accord with Doctor Henderson's conclusions.

As to the toxic effect of the gas itself, and relative to chronic CO poisoning, there does not seem to be accurate scientific information. Unless CO has a toxic action we would hardly expect to get chronic poisoning, as the mere lessening of the oxygen content of the blood to a minute extent for brief periods of time would hardly do any damage. The general opinion of physicians to whom I have talked and who come into contact with CO cases is that the gas is toxic and that there is such a thing as chronic CO poisoning, although they think men may acquire a tolerance for the gas. In our own experience I have not been able to separate the effects of exposure to CO from other factors of the occupation that might affect the health.

While engaged in cooperative work with the Bureau of Mines, we studied a group of men who were daily exposed to CO underground and who were often knocked out for brief periods. At no time did we ever find any evidence of CO in their blood, although it was sampled immediately when they came out of the mine. Their general health was impaired, but their work was

very arduous, hot, and dangerous and would sometimes last twenty-four hours or longer on a stretch, so that we cannot ascribe their condition entirely to CO. On the other hand, it is probable that our methods of analyzing the blood were not sufficiently delicate to reveal minute traces of CO. The war prevented this work from being concluded. However, it is not justifiable in the present state of our knowledge to allow men to be steadily exposed to CO, even in minute quantities.

In conclusion, I would like to state that the subject of carbon monoxide poisoning is one which industrial physicians whose patients are exposed to this gas should study carefully in the light of their own experience, and their findings should be reported. Furthermore, whenever men are overcome, or suffer from attacks of dizziness, weakness and prostration, without an adequate reason being at once apparent, the possibility of CO poisoning should be borne in mind.

MUNITIONS BODY LAUDS MEDICAL SERVICE

The *Lancet*, London, England, in its issue of January 18, 1919, discusses with the power of conviction the subject of Industrial Efficiency and Preventive Medicine. After pointing out the national peril of physical unpreparedness, the editorial summarizes the field of industrial medicine as follows:

"We desire to see every employer of labour with the whole or part-time services of a doctor at his disposal to advise him on welfare and health matters; to examine new workers; to watch over the health of his whole staff; to supervise the hygiene of his establishment as regards ventilation, light, temperature, cleanliness, and first-aid appliances; to advise and help the Welfare Department; to be, in fact, an industrial medical officer of health. Such officers should also be retained to advise the local employment exchanges as to the type of worker to be drafted to this or that trade or process. They should also be employed to conduct the periodical examinations of juveniles industrially employed, as will be required under the provisions of the Education Act, 1918, and so to coordinate the school and factory medical supervision. Such local officers would require to be directed and assisted by a medical organization controlled from headquarters—a nervous system of which the local service would be the peripheral end-organs. The value of such a medical organization, associated with the Government Department concerned with employment, would be incalculable not only to carry out investigations and assist research into the effect of industrial conditions and hours of labor, but also to influence the adoption of health reform based on sure knowledge so obtained. Probably in the whole field of preventive medicine nothing more urgently calls for action than the establishment of organized medical supervision of employment on sound lines; probably no field promises in return for cultivation a finer harvest of results. In the past unfavorable conditions of employment, overwork and fatigue have caused irritability and labour unrest, impaired physique and disease.

"The subject of industrial efficiency in relation to health and fatigue is in a large degree one of preventive medicine, a question of physiology and psychology, of sociology and industrial hygiene. . . . Without health there is no energy, without energy there is no output. More important than output is the vigour, strength and vitality of the nation." (From Report of Health of Munition Workers Committee.)

"Thus the final report of the Health of Munition Workers Committee in the sentences we quote summarizes the whole great truth. In the immediate future the nation, as never before, must obtain industrial efficiency through preventive medicine."

INDUSTRIAL MEDICAL AND DENTAL CLINICS IN THE WOMEN'S GARMENT TRADES

BY GEORGE M. PRICE, M. D., DIRECTOR, THE JOINT BOARD OF SANITARY CONTROL, NEW YORK.

THE time is fast approaching when medicine, surgery and dentistry will cease to be strictly individualistic professions. The social and economic progress of the age leads to a higher development of these professions. The socialization of these liberal professions is the next step which is inevitable and should be prepared for by progressive physicians, surgeons, and dentists.

Industrial medicine is a development which, though of recent origin, is bound to be greatly extended in the near future. There is no doubt that within the next decade or so every industrial establishment in the country will have its own physician, surgeon, dentist, and nurse. Just as it is a practice of every industrial establishment to attach to its plant an engineer to take charge of and supervise the technical elements in the factory, so will it appear reasonable and necessary to appoint in every establishment some one to take

charge of and supervise the human element in the workshop. Surely the human element in industry needs as close and as careful supervision as do the inanimate machinery and technical parts of the plant.

Six years ago, while directing the investigations of the New York State Factory Commission, I encountered in all the sixty thousand industrial establishments of the whole Empire State not more than a dozen industrial physicians and surgeons, and these poorly paid and not too competent. Now there are not less than three or four hundred industrial establishments that employ full-time industrial physicians and surgeons. There are, I believe, more than six or seven hundred members in the American Association of Industrial Physicians and Surgeons, and hardly a day passes when there is no addition to their number.

Industrial clinics in New York provide dental laboratories like this, and one or more dentists.

Ordinarily the industrial clinics attached to plants are measures of self-protection on the part of the employer. Especially since the enactment of the workmen's compensation laws has the employer found it to be to his greater advantage to appoint industrial physicians and surgeons for curative as well as for prophylactic purposes. The

women's garment trades of New York City and has been in existence for the last six to eight years.

In 1910, after the general strike in the cloak and skirt industry in New York City, during which sixty thousand workers conducted a bitter strike for ten or more weeks against the organized

The clinics for garment trades workers are managed by employees.

clinic is usually a part of the plant and is financed by the employer. It is also managed by him through the physician or surgeon whom he employs. A number of these clinics have also one or more dentists attached to them, as well as one or more nurses.

With industrial clinics established and financed by employers, it is but natural that the workers themselves are still under some apprehension and misconception in regard to the purposes and value of these clinics. One cannot blame them for fearing the gift that an employer imposes upon them. They look for the motive behind the employer's action. They fear that physical examination as conducted by the employer or his physician is simply a measure to weed out the "undesirable" employee. They know the Greeks and fear their gifts.

Few have been the attempts to create cooperative industrial clinics, clinics established by the workers and for the workers, and managed by them. Hence it may be of some interest to describe in more or less detail an experiment in industrial self-control which has been undertaken by the Joint Board of Sanitary Control in the

Cloak and Skirt Manufacturers' Association, a protocol of peace was signed on September 10, which was partly the work of Supreme Court Justice Hon. Louis D. Brandeis. Among the many provisions of the protocol, there was one which created a Joint Board of Sanitary Control, "said board to be empowered to establish standards of sanitary conditions to which the manufacturers and the unions shall be committed and which both sides obligate themselves to maintain to the best of their ability and to the full extent of their powers." In January, 1913, after another strike in the dress and waist industry, this industry was also taken over by the Joint Board of Sanitary Control, which then had jurisdiction over twenty-seven hundred industrial establishments in the two trades in New York City, in which were employed over seventy-five thousand workers, men and women.

The main work of the Joint Board of Sanitary Control consisted in industrial self-control, in surveying, investigating, and instructing over twenty-seven hundred shops in the two industries; in establishing standards of safety and sanitation, lighting, ventilation, etc., for these shops; and in

enforcing the standards not by police power or compulsion but by education, cooperation, and educational persuasion. The remarkable progress of the work of this board has been noted by many outside the city of New York, commended by the United States Department of Labor, which made several investigations of this institution, and has generally aroused great and intense interest in this new attempt by an industry to take charge of its own sanitary conditions.

Very soon after the establishment of the Joint Board of Sanitary Control, it became apparent that it is a difficult if not impossible task to improve the sanitary conditions of an industry without, at the same time, attempting to improve the conditions of health of the workers themselves. A physical examination of eight hundred workers in 1912 had disclosed a very large number of health defects among these workers, the need of a health campaign among them and the introduction of proper medical supervision. By educational methods and in cooperation with the leaders of the workers' organizations, certain locals, or

offices was then established in conjunction with the office of the board, and a large number of workers voluntarily appeared in the clinics for examination, advice, and treatment. In 1913 the United States Public Health Service cooperated with the Joint Board of Sanitary Control, and during the summer of that year not less than three thousand one hundred workers were given a most thorough physical examination, the results of which appeared later in the *Bulletin of the United States Public Health Service* on "The Health of Government Workers," No. 71.

Since its establishment in 1912, the medical clinic of the Joint Board of Sanitary Control made more than twenty-seven thousand examinations, the exact number on the first of January, 1919, being 27,640. The following is a table of the number of medical examinations made in the clinic during the last six years:

1912	1913	1914	1915	1916	1917	1918	Total
800	1234	4712	5229	7226	3415	5024	27,640

For the last two years the clinic has examined every applicant for membership to the union, the

Applicants for membership in garment trades union awaiting medical examination.

branches, of the union were induced to introduce so-called "medical benefits" to pay to their members during acute diseases certain sums of money for certain periods, also to take care of all those workers in the shops who, after a thorough medical examination, have been found to be suffering from pulmonary tuberculosis. A medical

unions having passed a law not to accept any candidates into their bodies without a preliminary medical examination in the clinic.

Clinics are conducted daily, between the hours of eleven and one, and five and seven. One or two sessions are conducted by a female physician, especially among the Italian women, who ob-

ject to an examination by a male physician. The equipment of the clinic is thorough, the laboratory is well equipped. Suspicious tuberculosis cases are given fluoroscopic examination. Blood pressure tests and urinalyses are made when need for them is indicated.

The clinic also supervises the various sick and invalid benefits which are given by the locals of the union. Thus a person claiming the benefit for an acute disease must pass through an examination, either at the office of the clinic, or at home if he is unable to appear in the clinic. Benefits are paid only after examination by the clinic. The unions also provide sanatorium treatment and cash benefits for all their members who are found to be suffering from pulmonary tuberculosis. These benefits are also supervised and managed by the clinic. During the last year the unions bought a large plot of ground—three hundred acres—and are at present collecting funds for building their own sanatorium for tuberculous workers.

All the work in the clinic is paid for by the labor organizations; the members themselves pay nothing except that those members who are not in good standing are charged a small fee for medical examination and treatment. An important extension of the work of the clinic is the nose, throat, eye and ear clinics, which are on a pay and co-operative basis. In other words, these clinics do not give gratuitous service but charge a nominal rate of \$1 for eye, nose, throat, and ear examinations, by specialists. These special clinics are conducted at special times.

Another important extension of the activities of the clinic is the dental clinic. This clinic is a unique establishment, in the fact that it is probably the first industrial cooperative, self-paying, dental clinic established, conducted, and managed by the workers themselves. The twenty-seven thousand examinations made in the medical clinic have clearly shown that a great many of the workers are suffering from defective teeth, and have likewise shown that a large number of these defects were directly contributory to various diseased conditions among these workers. Furthermore, it has been shown that the ordinary dental work which has been perpetrated upon the poor workers on the east side in New York City not only does not do them any good but does them real harm. Many of their dental defects are simply hidden and obscured by the gold crowns and bridges which are so lucrative to the dentist and so harmful to the patients.

The dental clinic is established to do thoroughly honest work in dentistry at a reasonable cost. The clinic employs a competent medical dentist who is

doing good work and whose purpose is not so much curative as prophylactic. Educational work in prophylaxis is carried on all the time and is the main purpose of the clinic. All work is done in the clinic, which at present employs two full-time and two part-time dentists. During the year 1918, the dental clinic treated 7,465 patients, and has had an income of \$12,576.73. It has practically paid for itself, although it had a slight deficit of \$292. The charges to patients are based upon cost, approximately \$2.50 being charged for an hour's work. Both the medical and dental clinics are very popular among the workers, and have proved successful in every respect.

The main significance of these clinics lies, of course, in the fact that they are conducted, financed, and managed by the workers themselves, for their own benefit.

REHABILITATION OF THE DISABLED

An international conference on rehabilitation of the disabled was held in New York March 18 to 21, 1919, under the auspices of the Red Cross Institute for Crippled and Disabled Men, and the Red Cross Institute for the Blind.

Representatives were present from the French Ministry of War, the Belgian Ministry of War, the Italian Ministry of Pensions, the British Ministry of Pensions, the British Ministry of Labor, the Canadian Department of Soldiers' Civil Reestablishment, the Canadian Department of Military Defense, the Surgeon General of the United States Army, the Federal Board for Vocational Education, the Bureau of War Risk Insurance, and the American Red Cross.

The conference was the most representative one of its kind ever held, and dealt with the multitude of questions raised by the programs of rehabilitation in the allied countries.

The main subjects discussed were: National Organization of Rehabilitation in France, Belgium, Italy, Great Britain and Canada; the American Program of Physical Reconstruction; the American Program of Compensation; the American Program of Vocational Rehabilitation; Functional Restoration; Bedside and Ward Occupations; Red Cross Recreational and Diversional Work in Military Hospitals; Provision of Artificial Limbs and Prostheses; Artificial Limbs and Other Prosthetic Appliances; Medical Service in Relation to Rehabilitation; Encouragement of Men to Undertake Training; and Morale during Training; Vocational Counsel, Industrial Surveys of Employment Applications for the Handicapped; Methods of Training; Educational Work in Military Hospitals; Relation of Pension, Compensation and other allowances to Rehabilitation; Interests of Disabled War Veterans Association; Organized Labor and Employers in Rehabilitation; Education of the Public; Rôle of Social Service; Rehabilitation of the Blind, the Deaf, and the Tuberculous; Rehabilitation of Crippled Children; Land Settlement for Disabled; and Placement of Disabled in Employment.

Chattanooga Maintains Wartime Clinic

The venereal clinic established in Chattanooga by the United States Public Health Service during the war will be continued in operation by the city.

THE PREVENTION OF TUBERCULOSIS IN INDUSTRY

BY D. B. ARMSTRONG, M.D., ASSISTANT SECRETARY, NATIONAL TUBERCULOSIS ASSOCIATION; EXECUTIVE OFFICER,
FRAMINGHAM COMMUNITY HEALTH AND TUBERCULOSIS DEMONSTRATION, FRAMINGHAM, MASS.

IN an article of this kind no attempt can be made to cover in a complete way the problem of tuberculosis prevention in industry. Indeed, many special phases of this problem have already been presented extensively and with thoroughness in the medical literature, from the point of view of statisticians, industrial hygienists, and others.

It is the intention here merely to relate certain phases of the Framingham experience acquired in the development of the program of the Community Health and Tuberculosis Demonstration. The work there has, of course, touched industrial problems and largely involved the industrial age group. From the point of view of the Framingham experience it may be worth while in addition to point out certain devices, largely routine in character, that have been employed in Framingham for the detection and control of tuberculosis in industry. This presentation should be considered in no way exhaustive; rather, it is suggestive only.

Before taking up tuberculosis findings in particular, it may perhaps be wise to present briefly the chief results of the medical examination work in Framingham, in so far as they are related to the industrial age group. As has been fully described in formal Framingham publications (particularly monograph No. 4), an effort has been made to examine a large percentage of the population of this normal civilian community. Up to the present time out of a population of 17,000, between 10,000 and 11,000 have been examined either in special medical examination campaigns, or through the normal workings of the medical machinery provided for infant clinics, pre-school summer camps, public schools, factory groups, etc.

From a statistical point of view the most reliable data have been derived from the special medical examination campaigns. Out of the 4,473 individuals examined thus far 1,716, or 38 per cent, fall in the industrial age of from fifteen to forty-four years. Certain rather interesting contrasts can be made between the industrial age group on the one hand, and the entire group of examinees on the other, equally distributed as the latter group was for age and sex, and for economic, social and geographic factors. These findings are presented in tabulated form, as in Table 1.

TABLE 1—ILLNESS IN INDUSTRIAL AGE GROUP AND ENTIRE GROUP OF EXAMINEES

	Total Examined	Per Cent Ill	Per Cent Examined Seriously Ill	Per Cent of Total Illness Serious
Entire Group ...	4473	77	25	32
15-44 years	1716	71	26	37

From this table, it will be noted that the entire group presented a higher percentage of illness from all causes than the group of ages fifteen to forty-four. The ratio is 77 per cent to 71 per cent. It may be stated in this connection that for the 77 per cent recorded as ill, following a classification of illness according to preventability, 64 per cent were classified as preventable, and 22 per cent as partially preventable, leaving only 14 per cent of all this sickness as strictly non-preventable.

An attempt to divide the illnesses into major serious affections and minor affections, indicated that of the 4,473 examined, 25 per cent were seriously ill. This serious illness constituted 32 per cent of the total amount of illness. For the industrial age 26 per cent of those examined were recorded as suffering from a disease of major importance; these serious affections constituted 37 per cent of the total amount of illness in this age group. It would seem from this that the industrial age is more likely to suffer from the more serious affections.

As economic conditions are directly related to industrial welfare, a distribution of illness according to income groups may also be of interest. This may be indicated as follows on a basis of the annual family income:

\$700 or under.....	77 per cent ill
\$700 to \$1,200	77 per cent ill
\$1,200 to \$1,800	69 per cent ill
\$1,800 and over	65 per cent ill

The distribution of illness according to the main industrial occupations in Framingham is as follows:

Foundry and machine shop.....	70 per cent ill
Paper products	73 per cent ill
Shoe manufacturing.....	78 per cent ill
Woolen industry.....	82 per cent ill

The experience in Framingham has shown, however, that any distribution of illness according to one factor alone without giving full consideration to other possible influences, such as age and sex distribution, race stock, etc., is likely

to be misleading. While the industrial classification of illness just given may be somewhat suggestive, it is, therefore, to be taken, as presented, with considerable reservation as to final judgment.

As to the prevalence of tuberculosis, it may be stated that the findings in Framingham are in no way unique, as regards industry. There is the usual excessive distribution of tuberculosis cases to the industrial age group. Examination work among industrial groups has disclosed an average prevalence of tuberculosis. The whole question of distribution of tuberculosis cases according to age group, with special reference to the industrial period sixteen to forty-five years for the different types of tuberculosis cases as classified in Framingham, may be indicated most concisely in Table 2.

TABLE 2—DISTRIBUTION OF TUBERCULOSIS CASES ACCORDING TO AGE GROUP

Groups of cases during demonstration—	Total all Ages	16-45 Years	Per Cent in Industrial Age
Deaths	29	16	55
Cases lost to other communities..	32	21	65
Cases under treatment in out of town institutions	22	15	68
Cases under treatment at home..	159	94	59

It will be noted that for these several groups the percentage falling in the industrial age ranges from fifty-five to sixty-eight. That is to say, whatever the classification of cases, more than half are found in the industrial age period. This, of course, confirms previous data bearing on the special burden which tuberculosis places upon industry.

In Framingham, of course, an effort has been made to meet this situation. Considerable co-operation has been secured from local industries, and a program developed for the industrial situation as a whole has up to the present time been in part applied. On a basis of this experience it may perhaps be timely to attempt to indicate in a brief, obviously incomplete, and cursory manner the various instruments upon which an industrial community may depend for protection against disease in industry, particularly tuberculosis. The devices and channels of approach to the industrial health problem may in part be indicated as follows:

General Community Hygiene

General sanitary conditions in the community, housing conditions, etc., are reflected in industry through the manner in which these outside environmental conditions affect the individual worker. No program of industrial hygiene can be complete which does not consider the family

welfare of the industrial worker and the hygiene of his general social environment.

Industrial Organization

Employment and Industrial Adjustment.

The modern factory is beginning to recognize the economic as well as the hygienic advantage of a competent employment manager. The work of this individual should be closely related to the medical department. Men at the time of employment should be given consideration as to their physical and mental status, from the point of view of their adaptation to the work to be undertaken. The medical work in the industry, the physical examination and nursing activities, should aim, not at the elimination of the unfit from industry, but, in cooperation with the employment manager, at the adjustment of the less fit to appropriate occupations in the industry. This problem is, of course, coming to the fore in a striking manner at present in conjunction with the work of industrial rehabilitation following demobilization.

Properly managed, there is no economic loss to industry in the adaptation of certain individuals to part-time employment. If cooperation can be secured from industrial managers in this regard, an important channel may be opened for the industrial realignment of arrested cases of tuberculosis fit to work only on a part-time basis at the start.

Medical Organization.—For an industry of twenty-five hundred employees it is believed that an adequate medical staff will consist of one full-time physician, two nurses, and possibly a dentist. There should then be maintained an industrial clinic always open to employees during factory hours. Larger industries will, of course, require a greater personnel, while for smaller plants, it is believed that an arrangement could be worked out whereby medical and nursing service might be sold on a self-supporting basis to the smaller plants on a part-time arrangement, under joint industrial, or perhaps outside responsible health auspices.

This medical and clinic equipment should provide emergency medical care for the industrial workers and should perfect an arrangement whereby cases of a non-emergency, chronic, long-standing character should be referred to an outside private physician of the patients' own choosing for treatment.

An important function of the medical staff should be the routine, thorough medical examination of employees. This should certainly be compulsory for all new employees and may be carried out on a compulsory or voluntary basis for permanent employees.

In communities where the industrial workers are organized, their cooperation and support is essential to the success of medical organization in industry. In certain sections, indeed, the organized workers have taken the initiative in the matter and are themselves employing the medical and nursing staff.

Nursing Organization.—In addition to the work which the nurse must do to assist in the medical activities as outlined above, there may also be cautiously developed through the nursing staff a certain amount of outside work, in the homes of the employees, along social relief, educational, and hygienic lines. Any outside industrial nursing work should always be done in closest cooperation with established community, district, or public health nursing agencies.

Educational Work.—In the industry itself, as well as in the homes of the workers, the greatest emphasis should be placed upon the practice of personal hygiene. Personal hygiene is the keynote of modern sanitation. On the success of the educational movement to promote personal hygiene depends our control of many of the chief causes of unnecessary disease and premature death, such as pneumonia, influenza, and the other respiratory diseases. Emphasis should be placed, at the present time, particularly on the dangers of careless respiratory contact, the dangers of sneezing, coughing, and spitting, the desirability of clean hands before eating, the dangers of common utensils, such as cups, towels, etc. The constructive, health-creative aspect of personal hygiene involving such measures as exercise, rest, fresh air, food, etc., should not be neglected in any educational campaign.

The Sanitation of the Plant.—This should, of course, be under the supervision of the medical staff, in cooperation with the safety engineer, if one is employed. Under this head will come such general matters of sanitation as ventilation, heating, the control of dangerous dusts and fumes, the elimination of dry sweeping during working hours, etc. Many items of equipment in industry bear an important relation to the practice of personal hygiene and to the avoidance of dangers from direct or indirect human contact. In this connection there are the questions of drinking facilities, proper arrangements for eating, toilet and washing facilities, control of spitting, etc.

Obviously, the problem of tuberculosis in industry is a matter, first, of the provision of machinery for the detection of disease; second, the establishment of measures for the control and eradication of tuberculosis and the adjustment of

arrested cases to a fitting occupation; and third, the development of a program of prevention along medical, hygienic, and educational lines. Industry is coming more and more to recognize that it bears an obligation to the man in industry as well as to the machine. Aside from the human values involved, the protection of the producer in industry has always proved to be, even when carried out haltingly and incompletely, a profitable investment of space, funds, and personnel.

Britain Reduces Industrial Diseases

England is achieving a rapid advance in the amelioration and control of industrial diseases in the trades affected by the Factory and Workshop Act, according to facts apparent in the comparative statistics for the month of November and the preceding eleven months, as against the number of cases reported in the year preceding. During the eleven months ended November, 1918, the total number of cases of poisoning and of anthrax reported under the act was 243, compared to 623 in 1917.

Announces Journal of Industrial Hygiene

The *Journal of Industrial Hygiene* will make its appearance in May under the editorship of Dr. David L. Edsall, of Harvard University, and associated editors as follows: W. Irving Clark, M.D., Alice Hamilton, M.D., Yandell Henderson, Ph.D., William N. Howell, Ph.D., M.D., Sc.D., LL.D., J. W. Schereschewsky, M.D., C.-E. A. Winslow, M.S., A. F. Stanley Kent, D. Sc. (Great Britain), Harry E. Mock, M.D., Cecil K. Drinker, M.D., and Katherine R. Drinker, M.D., will act as managing editors. The magazine will be devoted to industrial hygiene and community hygiene in relation to industrial welfare.

The Physician in Industry

With respect to the endeavors of leaders in the war industries of this country and England to prolong and increase the productivity of war workers and tradesmen in industry, the *Journal of the Iowa State Medical Society* calls attention to the results achieved in promoting individual efficiency and predicts that the investigations and recommendations of those engaged in that work will lead to a much wider range of health activities than has in the past been contemplated. It will bring about an adjustment of the professional field of medicine so that industry may derive the benefit of medical science in a fuller measure, while also protecting the physician in his professional status, the Journal asserts.

Army Physicians and Industrial Work

The National Safety Council expects the physicians returning from the war to be prepared especially to enter industrial service. In a recent bulletin it said:

"The Medical Corps of the United States Army has gathered together some of the best men in the medical profession and has given them special training in epidemiology, vital statistics, water supply, sewage disposal, and related branches. The cessation of hostilities leaves no work for these men in the army. Here is an opportunity for industries to secure trained sanitarians for plant work and for community work. If your plant or your community has no competent sanitarian or health officer, write to the American Health Association, 169 Massachusetts avenue, Boston, Mass. That association will send you, without charge, the names and qualifications of men who have left the Army Medical Corps."

LIGHTING CODE FOR WORK PLACES

In a statement published in the *Public Health Reports* for January 24, 1919, the divisional committee on lighting of the advisory committee on labor of the Council of National Defense sets forth a code for lighting factories, mills and work places. The prefatory note states that "when adequate and satisfactory illumination is substituted for the all too prevalent poor illumination in factories, mills and other work places, the results obtained are mutually beneficial to the employees, the employers and the country as a whole. Under proper illumination conditions the health, contentedness, safety, and skill of the employees are maintained at a high standard, the output is increased in quantity and improved in quality, while there is a proportional reduction in the cost of each unit of finished product when it reaches the public."

The requirements for good lighting are summarized under five heads:

1. Sufficient illumination should be provided for each workman, irrespective of his position on the working space.

2. The lamps should be properly selected and so installed as to avoid or minimize strain on the eyes of the workmen. The type and size of lamp should be adapted to the particular ceiling height and class of work in question.

3. The lamps should be operated from sources of supply which will insure continuity of service and steadiness of light.

4. Adequate illumination should be provided from overhead lamps, so that sharp shadows may be prevented as much as possible and in such measure that individual lamps close to the work may be unnecessary except in special cases.

5. In addition to the illumination provided by overhead lamps, individual lamps should be placed close to the work if they are absolutely necessary, and in such cases the lamps should be provided with suitable opaque reflectors.

The code is divided into rules and general information and suggestions. The rules are six in number and are briefly stated in the report:

Rule 1. General Requirement. Working or traversed spaces in buildings or grounds shall be supplied during the time of use with artificial light in accordance with the following rules when natural light is less than the intensities specified in rule 2.

Rule 2. Intensity Required. The desirable illumination to be provided and the minimum to be maintained are given in the following table:

	Foot-candles at the work		
	Ordinary practice	Minimum	Maximum
(a) Roadways and yard thoroughfares	0.05-	0.25	0.02
(b) Storage spaces	50-	1.00	.25
(c) Stairways, passageways, aisles,....	.75-	2.00	.25
(d) Rough manufacturing, such as rough assembling, rough bench work	2.00-	4.00	1.25
(e) Rough manufacturing, involving closer discrimination of detail... .	3.00-	6.00	2.00
(f) Fine manufacturing, such as fine lathe work, pattern and tool making, light-colored textiles.....	4.00-	8.00	3.00
(g) Special cases of fine work, such as watchmaking, engraving, drafting, dark-colored textiles.....	10.00-15.00		5.00
(h) Office work, such as accounting, typewriting, etc.	4.00	8.00	3.00

Rule 3. Shading of Lamps. Lamps shall be suitably shaded to minimize glare.

Note.—Glare, either from lamps or from unduly bright reflecting surfaces, produces eyestrain and increases accident hazard.

Rule 4. Distribution of Light on Work. Lamps shall be so installed in regard to height, spacing, reflectors, or other accessories as to secure a good distribution of light on the work, avoiding objectionable shadows and sharp contrasts of intensity.

Rule 5. Emergency Lighting. Emergency lamps shall be provided in all work-space aisles, stairways, passageways and exits to provide for reliable operation when, through accident or other cause, the regular lighting is extinguished. Such lamps shall be in operation concurrently with the regular lighting and independent thereof.

Rule 6. Switching and Controlling Apparatus. Switching or controlling apparatus shall be so placed that at least pilot or night lights may be turned on at the main points of entrance.

The remainder of the report is taken up with explanations and suggestions which are briefly but clearly stated.

DEVOTES DEPARTMENT TO INDUSTRIAL MEDICINE

Beginning with the issue for January, 1919, the *California State Journal of Medicine* is conducting a Department of Industrial Medicine. The reasons for this department and the functions it will endeavor to subserve are set forth thus in the December issue of the *Journal*:

"Physicians have learned many lessons from their military experience. They have learned discipline and organization. This lesson will be speedily taken to heart in the approaching development of group diagnosis and treatment. The future organization of the profession will be compact and closely related to governmental insurance problems, industrial needs and a better understanding of public health needs. Doctors must organize as they have never organized before, or their economic independence will cease."

"Physicians have learned many lessons in preventive medicine. The enormous impetus to industrial development in the era ahead, together with the large recognition of the responsibility of the public and the employer for the worker and his health, will force the physician to exercise an intelligent interest in industrial medicine.

"It is safe to say that the language of industrial medicine and compensation insurance is today a sealed tongue to the majority of the physicians of California, especially outside the chief cities, and even there exists a serious ignorance of the meaning and importance of industrial medicine. Occupational hazards, sanitation of industries, and hygiene of workers are alike strange. The principles of industrial accident compensation, the part the state now plays and is destined to play, the practical opportunity and duty of the individual doctor are unrecognized. He needs information on the elements of these topics. He needs to be kept informed of significant tendencies in these lines. He needs to keep in touch with industrial welfare work, both city and rural, both in California and elsewhere. He needs information on group organization. He needs must understand the function and opportunity of the physician in this enormous field, ranging from hygienic care and selection of workers, through occupational diseases and hazards, to the professional diagnosis and care of the victims of industry."

"To meet these needs the Department of Industrial Medicine is planned. Contributions, advice, opinions, experience are solicited."

The Texas Public Health Association enlisted 300,000 children in its health crusade in 1918, according to data presented at the association's annual meeting.

Dr. C. D. Selby, of Toledo, O., who helped to organize the new Division of Industrial Hygiene and Medicine of the Department of Labor, has returned to Toledo, but will continue to serve the division as consultant.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C. E. A. WINSLOW, DR. P. H., *Editor*

ORGANIZING MEDICAL SERVICE

IN the early days of the public health campaign there was a sharp line between curative and preventive medicine; and in what was called "preventive medicine" engineering and bacteriological activities predominated over those of a really medical nature. Today, however, the problems which engage the major attention of the public health officials—the campaigns against infant mortality and tuberculosis, and venereal disease, the control of the communicable diseases of childhood, and the reduction of the death rate from the constitutional disorders of adult life—are problems which must be solved not by control of the environment, but by altering the habits of the individual. The engineer and bacteriologist give place to the physiologist and hygienist. Furthermore we are interested not only in teaching the broad principles of personal hygiene as applicable to every one, but in bringing to the individual the knowledge that he needs to enable him to use his particular human machine with its incipient physical defects to a maximum of advantage. Such education implies the diagnosis of the beginnings of disease and means that the gap between the clinician and the public health official must be bridged.

From the standpoint of the physician a rapprochement is equally desirable. Sanitation has achieved notable triumphs, but in spite of the advances in the science of medicine there is as yet little to show in the actual reduction of the disorders which have their origin in the faulty operation of the human machine. The fruits of medical science cannot be garnered until medicine becomes truly "preventive"—until the physician can apply his knowledge at an earlier stage than is possible under the present system of medical service.

The best method of organizing medical service for the prevention as well as the treatment of disease remains to be worked out, and we do not

yet know whether this end will be effected by the development of public and private clinics, by the introduction of systems of health insurance, or in some other way; but the solution of this problem promises to be the central issue in the public health campaign during the next decade. If the columns of MODERN MEDICINE can supply a forum for the discussion of this question it will render a real service, alike to the medical profession and to the public.

EDITOR.

GOOD ROADS AND HEALTH

THERE are fewer physicians in the rural sections of the country than in the cities; there are very few nurses, and practically no hospital facilities in rural regions. In some communities, even in the older states, there is only one physician to 1,500 people and many cases can be found where there is only one physician to 3,000 people, while the average for the cities is generally about one physician to 650 people.

The inadequate supply of physicians in the country is not due to the superior health of the people; there is just as much work needing to be done by the physician in rural as in urban sections. The reason is rather to be found in the lack of means of getting around the country without extreme hardships. It is becoming harder and harder for the young medical graduate to choose a rural location where he must face intolerable traveling conditions for the greater part of the year. After nine years of training for his profession, there is small appeal in the prospect even of a good practice, when the hardships of travel over the country roads are taken into account. Yet hundreds of young medical graduates would by inclination favor a rural practice if it were possible to avoid the unhappy features of country travel. The problem is important to physicians, not only because it is difficult to travel through mud to see their patients, but, also, because it is quite difficult if not im-

possible to transport patients needing special care, or to consult with specialists at a distance or to counsel with other general practitioners.

The results of these conditions have been serious. The death rate of the country districts is only slightly lower than the city and has not improved as rapidly as in the city; the sickness rate is no more favorable; the proportion of young men physically unfit for the army was nearly as great in spite of the boasted physical prowess of the country, and all surveys have proved that a higher percentage of curable defects is found among rural children than among city children.

But there is a worse condition still. The number of deaths of women in childbirth is proportionately greater in the country, and the number of babies who die within the first thirty days after birth is far greater. Forty per cent of all the babies that die in their first year in the cities die within thirty days after birth, while the corresponding figure for the country districts is 47 per cent. No better index of medical care could be given than these facts. They tell the story that nearly every one knows; viz., that adequate medical care is not available for the rural mothers and babies.

Good roads would enable the rural sections to secure nursing and specialists' services which are now practically impossible in many sections. Much of the future development of public health work, visiting nursing and medical service generally in the rural communities depends upon the development of good roads. It is quite impossible to provide such service effectively under present conditions.

There is also looming up the possibility of a rural hospital service with facilities for transportation to, and care in, community hospitals in which the facilities for diagnosis and care would far exceed the meager provisions of the home. The coming of good roads will hasten this development.

The city residents are concerned also in the condition of rural roads from the standpoint of health protection because they are dependent upon good roads for fresh milk. Large cities are furnished milk from remote rural regions. Bad roads delay its delivery. It is not uncommon for milk to be allowed to accumulate for two or three days before delivery from the farm. Bacteria often develop dangerously in the meantime. Good roads will emancipate the cities from depending upon existing clumsy means of transportation.

General Gorgas Heads Yellow Fever Commission

Major General William C. Gorgas, recently retired for age from the office of Surgeon General of the United States Army, has resumed his position as chief of the

Rockefeller Commission on Yellow Fever and will soon sail for Central America to supervise the studies that are being carried on there by the Rockefeller Commission.

Physicians Give Services to Schools

In response to the appeals of women's organizations in Kansas City for some form of medical examinations in the schools, thirty-two public spirited physicians are voluntarily giving their services for this purpose.

Health Officers Study Infectious Diseases

Dr. Charles C. Duryee, of the sanitary division, State Health Department of New York, is conducting a post-graduate course for physicians and health officers in the study of infectious diseases and public health at the Albany Medical College. The department of health and the college are cooperating in the undertaking.

Medical Aid Free to Former Soldiers

Free medical attention is the right of any man accepted for military duty during the war and later discharged for physical disability resulting from injury or disease in line of duty, says a statement issued by the war risk insurance bureau. Treatment will be provided by the bureau of war risk insurance to all men who are 10 per cent disabled and can trace their disability to military or naval service.

Government Experts Study Mental Hygiene

The coordination of work in all government bureaus and state health departments, in so far as the problem of mental hygiene, insanity and mental diseases enters into the efforts of each, will be undertaken by the United States Public Health Service. A brief of the bureau's program for the investigations in this direction is printed in *Public Health Reports*, Vol. 34, No. 7. Measures for the prevention of mental disorders and consideration of occupational causes of mental disorders, the application of the immigration laws, and child hygiene will receive study.

Urges Compulsory Study of Venereal Diseases

Mr. Justice Hodgins, royal commissioner of the Ontario government, recommends that medical students in Ontario be required to pursue a compulsory course of study in venereal diseases. This recommendation is contained in a report submitted by the commissioner, supplementary to the annual government report on venereal diseases. He proposes the creation of a body to be known as the Ontario Social Hygiene Committee, to conduct educational propaganda. He criticizes the limitation on the production and sale of salvarsan which the owners of the patents compel.

Creates Joint Influenza Committee

A Joint Influenza Committee has just been created to study the epidemic and to make comparable, so far as possible, the influenza data gathered by the government departments. The members of this committee, as designated by the Surgeon General of the Army, the Surgeon General of the Navy, the Surgeon General of the Public Health Service, and the Director of the Census, are: Dr. William H. Davis, chairman, and Mr. C. S. Sloane, representing the Bureau of the Census; Dr. Wade H. Frost and Mr. Edgar Sydenstricker, of the Public Health Service; Colonel D. C. Howard, Colonel F. F. Russell and Lieutenant Colonel A. G. Love, United States Army; Lieutenant Commander J. R. Phelps and Surgeon Carroll Fox, United States Navy.

THE NEW PUBLIC HEALTH

BY H. W. HILL, M.D., D.P.H., EXECUTIVE SECRETARY MINNESOTA PUBLIC HEALTH ASSOCIATION, ST. PAUL, MINN.

NEW views of public health principles have been slowly forming for a decade. The fundamental change from the old consists in a shift of attention from the inanimate surroundings of man—his house, his dooryard, his clothes, air, food—to the man himself. Previous generations of public health propagandists had been so intent on the importance to the individual of his health that they quite overlooked the importance to that health of the individual; that is, they overlooked the immense importance in arriving at the climax—health—of those factors involved in the individual, his make-up, his vigor, his alertness, his enterprise, his physical adaptability, his faculty for meeting adverse conditions.

To these previous generations health had come to be something which inanimate surroundings might impose or might deny, irrespective of the individual concerned, who was, in their conception, a mere plaything of environment.

We of the new views realize that, always barring infection, the health of any individual is far more a matter, first, of his congenital physical equipment and, second, of a certain "sweet reasonableness" in his conduct of his own body operations than of surroundings, be the latter "good" or "bad" on the older schedules.

But, alas, infection cannot ever be ignored, so long as our world remains in its present state. Here again the New Public Health differs from the old in turning from inanimate surroundings, air, water, house, soil, etc., as infectious sources, to the animate surroundings—to the individual's biological associates, man, beast, bird, insect. Thanks to Chain, these have been proved for most infections the only breeders of disease and its chief distributors.

The latest most definite change in views the New Public Health has adopted still awaits general recognition. Our recent world outbreak of influenza has called attention to it and forced it with brutal frankness even on those most inertly anchored to the older views; but these are now

THE NEW PUBLIC HEALTH

This, then, means a high regard for heredity in its broadest sense; a profound respect for immunity, be it hereditary or acquired; a deep distrust of contact between immunes and infected associates; and a glad rejection of the "laws of health" as a protection against infection.

These "laws" were as minute as the Talmud's and were just as barren of protection against disease as were the Talmud's against immorality.

The latest most definite change in views the New Public Health has adopted still awaits general recognition.

bull and then by bear. They held that this "resistance" fluctuated—chiefly downwards—with the surroundings, with extraneous conditions, a missed meal, an hour's extra walk, loss of a night's sleep, etc.

Persons physically imperfect, of poor development, below par in any way, were in that view more subject to infection than their more stalwart neighbors. He who did not possess a good physique to begin with, or who, whether possessing a good physique originally or not, failed to observe the "laws of health" regarding diet, sleep, exercise, brushing his teeth, "changing his feet," etc., invited all sorts of diseases, but particularly the respiratory.

Now, if we never learned anything before from any observations on diseases and their respective specific immunities, the influenza epidemic has surely taught us one thing, with its six million deaths in two years (all but equaling the deaths of the Great War in four years!). It has taught us that whatever "resistance" is or does, it does not correspond with the outward signs of good physique and is not affected by surroundings (unless they be beyond all body compensations), nor does it fluctuate with every little incident in daily life. Take merely the broadest facts now known to everyone. In the influenza outbreak, who escaped—the vigorous adult in the prime of life? No—he was the favorite victim! Who, then escaped—anyone? Yes (at least relatively)—the child, the aged and the tuberculous. There is no evading this world-demonstration so widely manifested that almost every survivor, lay or profes-

adrift, have not yet re-anchored. We propose to show them the only place where they can re-anchor safely.

This older view, long fully recognized as futile by a few leaders, regarded each individual as possessing a certain "resistance" to infection, as he might possess certain stocks in the Wall Street market. The value of this "resistance," so they held, varied as wildly as some Wall Street stocks do when raided first by

They held that this "resistance" fluctuated—chiefly downwards—with the surroundings, with extraneous conditions, a missed meal, an hour's extra walk, loss of a night's sleep, etc.

sional, has seen the proof with his own eyes amongst his own friends or relatives—a demonstration by first-hand observation, hitherto reserved to those few physicians who deal with contagion as a business.

We do not know why vigorous middle-age succumbs or why the feeble and the tuberculous escape. But not the most crassly ignorant or prejudiced can fail to see that the relation usually predicated between physique and "resistance" is *not* the explanation; indeed this must be reversed if it could even remotely be forced to fit the only too plainly revealed facts.

The New Public Health, then, means a high regard for heredity in its broadest sense; a profound respect for immunity, be it hereditary or acquired; a deep distrust of contact between non-immunes and infected associates and a glad rejection of the laws of health; *as a protection against infection.*

These "laws" were as minute as the Talmud's and were just as barren of protection *against disease* as were the Talmud's against immorality. The fear of hell was the old argument for morals—the hope of a happy, successful, honored life, the new.

Cleanliness Serves Its Own Purpose

The fear of infection (typhoid, tuberculosis, etc.) has been long the argument for cleanliness and decency in physical life—but the New Public Health now recognizes the benefits of cleanliness, exercise, etc., as quite sufficient in themselves, without adding as their preposterous chief virtue protection from infection, a virtue now shown to be, in practice, nonexistent.

Having said so much with all the emphasis we may, permit another paragraph, this time of appeal against the inevitable, lamentable bore who will, without doubt, say that we throw cleanliness and decency to the winds, because we insist these have not saved our millions from disease and death due to infection. Such clamors will arise. We point all clamorers to the facts—let them explain them. Nor do we wish that our more sober critics should mistake us as condemning in any sense that which is a real bulwark against most infection—the "cleanliness" of the trained surgeon, physician, nurse, brought to technical perfection and conducted in the presence of contagion with alert knowledge and intent minuteness.

The cleanliness and decencies of ordinary life—the bath, the tooth brush, the mouth wash, the change of clothing on occasion, the swept floor and the clean bed sheets, the dusted piano, and the oft-scrubbed garbage pail—it is not such cleanliness and decency, fine as they are in themselves,

that offset infection, yet, alas, popular Public Health has taught it so for decades.

One last appeal—*please* do not quote us as maintaining that there is no such thing as resistance. Resistance exists; it is the most important weapon that we have to meet infection with—and will be, until such time as we succeed in abolishing infection. What the New Public Health maintains is this, that such resistance is not a function of the physique, and does not fluctuate with every little factor of ordinary life. Perhaps it fluctuates, but if so, the factors of that fluctuation are still unknown.

SCHOOLS WANT UNIFORM HEALTH COURSES

At the invitation of Yale University, several eastern universities sent members of their faculties to New Haven recently to confer on the problem of standardization of the curricula and degrees conferred by colleges in the field of public health. A resolution was approved defining degrees for Doctor of Public Health (Dr.P.H.), Doctor of Science in Public Health or Hygiene, Certificate of Public Health, and Bachelor of Science in Public Health or Hygiene. Dr. W. H. Welch represented Johns Hopkins University, Prof. W. T. Sedgwick attended for the Massachusetts Institute of Technology; Dr. M. J. Rosenau, for Harvard; Dr. W. H. Park, for New York University; Dr. H. F. Smith, for the University of Pennsylvania; and Professors S. E. Barney, L. B. Mendel, L. F. Rettger, M. C. Winteritz, and C.-E. A. Winslow, for Yale University.

The text of the resolution adopted is as follows:

1. That the degree of Doctor of Public Health (for which the abbreviation should be Dr.P.H.) for graduates in medicine should normally be awarded after two years of work done under academic direction, of which one year at least should be in residence and that the requirements for the degree should include class work, practical field work, and an essay based on individual study of a particular problem.

2. That the degree of Doctor of Philosophy or Doctor of Science in Public Health or Hygiene should be conferred on students who hold the bachelor's degree from a college or technical school of recognized standing, and have satisfactorily completed not less than three years of graduate study. It is understood that this degree is based on the fundamental sciences associated with hygiene and public health, including a knowledge of physics, chemistry, general biology, anatomy, physiology, physiologic chemistry, pathology, and bacteriology, in addition to the thesis and usual requirements for the Ph.D. or Sc.D. degree.

3. That the Certificate in Public Health should be granted for not less than one academic year of work to those who have received a bachelor's degree from a recognized college or technical school, or have satisfactorily completed two years of work in a recognized medical school, provided they have previously pursued satisfactory courses in physics, chemistry, biology, and bacteriology.

4. That the degree of Bachelor of Science in Public Health or Hygiene should be given for the completion of a four years' course, the last two years of which have been devoted to the fundamental sciences associated with hygiene and public health or hygiene.

5. That the authorities having the appointment of health officials be urged to give preference so far as possible to persons holding degrees in public health or hygiene.

A SMALL PUBLIC HEALTH LABORATORY

BY GEORGE S. LUCKETT, B.A., M.D., FIELD DIRECTOR, COVINGTON COUNTY (ALA.) SANITARY CAMPAIGN,
ANDALUSIA, ALABAMA

IN several Alabama counties the state board of health has established sanitary units which are expected to demonstrate the practical worth of a well organized county health department. A small laboratory, capable of handling all routine examinations usually considered as falling within the scope of public health work, has proved a valuable adjunct to this particular unit.

It may be expected to secure more hearty co-operation of the physicians in the county when its full value to them has been demonstrated. A local laboratory is able to give more prompt reports than is often possible when specimens must be sent to the state health department, while the convenience in getting material to it seems to encourage the use of exact diagnostic methods. Proof of its worth was had at the very outset, when 2,007 diphtheria cultures were incubated and diagnosed within forty-eight days, during an epidemic in Andalusia.

The examinations of water and milk are appreciated by the more intelligent laymen and enlist their interest and cooperation. The added value of having a sanitarian on the ground to inspect conditions surrounding the source need hardly be mentioned.

It was with these considerations in mind that the director of the sanitary campaign in Covington County equipped, and has in operation, a small laboratory for the health department of that county. Nothing original is claimed for it, but this brief description is offered in the hope that it may encourage others to make the same venture and be of help in answering some of the questions that may arise as well as in avoiding some mistakes.

Any community that can afford a health unit should be able to support such a laboratory, while it would serve equally well for a large industrial plant maintaining welfare service, or, with some additions, as a business enterprise in a small city.

Much depends upon the versatility of the person chosen to conduct the work of the laboratory. It is not necessary to employ a full-fledged bacteriologist. Any young man or woman who has had training as a technician with subsequent practical experience in a hospital or general laboratory can handle all of the work that is offered, especially if at times the director can give a little help. In this instance the plan works well and the technician acts as secretary to the director.

The salary should be between \$75.00 and \$100.00 a month, depending upon the amount of training and experience demanded. However, there should be no stinting in this item of salary, as the success of the undertaking depends upon the industry, efficiency and whole-hearted loyalty of the laboratory worker.

Having secured such a person, it is well to take him into full consultation as to plans for equipping and operating his department. His preferences should be given every consideration possible as to types of apparatus and methods of procedure, thereby assuring his interest in his duties and contentment in a community that is often far from home and lacking in the diversions found in larger centers of population.

At the outset there should be considerable limitation to the scope of work undertaken by the small organization. Examination of the sputum for bacilli, of the blood for malarial organisms, of cultures for diphtheria, of the stools for parasites, of the spinal fluid for bacteria and cells, the Widal test and bacteriological studies of water and milk are all that can be undertaken successfully. The Wassermann test is employed so infrequently in the rural community that to maintain facilities for its performance would entail undue expense and it can well be left to the state labo-

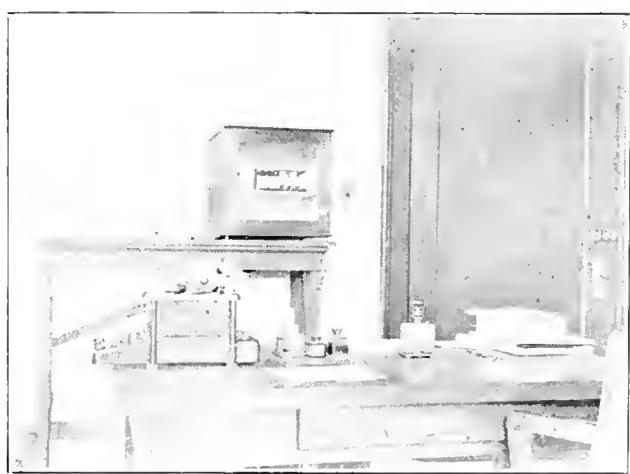

Fig. 1. Sterilizer.

ratory. The latter should also handle the brains of supposedly rabid animals, as some experience is required in such an examination, especially if confidence is to be placed in a negative report.

In addition to the regular lines, it is often desirable to do some clinical work for the local

physicians at a nominal charge. In the present instance a demand was made at once for such service. Without interfering greatly with the proper functions of the laboratory, it is possible to do routine urinalyses, blood counts, gastric analyses, occult blood tests and other simple pro-

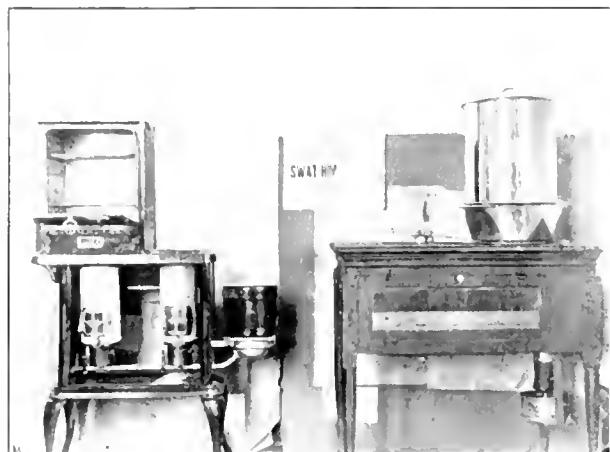

Fig. 2. Portable baking oven with glass door substituted for the usual and more expensive hot air sterilizer.

cedures. The fees from such work are a welcome assistance in paying the running expenses, but are kept low enough to encourage better diagnosis by frequent resort to these aids.

For future reference and as a protection in case of disputes a simple record is kept of the results of each examination. This is easily accomplished by means of a card file arranged by patients' or physicians' names. There is also a tally sheet, on which the various kinds of examinations are noted for statistical purposes. Reports to physicians are made on a printed form which saves time and labor.

In announcing the opening of the laboratory it is well to send out a folder of attractive appearance, giving detailed descriptions for preparing and transmitting specimens. Otherwise, one is likely to have the experience of the writer, who was told by a physician that there was something wrong with the Loeffler's medium furnished, for it was so hard that he "could not push the swab into it at all." This folder should be sent out at frequent intervals, for it is sure to be under an accumulation of last year's journals when the busy doctor happens to need it. Accompanying this announcement and all empty containers furnished is a printed form on which the physician is requested to give necessary data.

Constant publicity will do much toward educating profession and laity alike to a full use of the facilities offered. A brief monthly letter to physicians, dwelling upon a particularly timely examination, is of considerable help. Articles in local

newspapers inform the public of the advantages offered by the laboratory and create a demand which the physician will do well to heed. They also bring calls for water and milk examinations. A little paid advertising along this line is also worth while. If a county laboratory is located in the court house, where it properly belongs, some simple cultures, with appropriate labels, can be kept on exhibition, along with graphic charts on health subjects. In other words, let people know you are there and "on the job."

As to cost, the Covington County laboratory was established at the close of the war, when purchases had to be made wherever obtainable and, often, regardless of cost or distance. With the rapid readjustments in business now in progress the problem will become greatly simplified. Bearing these facts in mind, the following figures will give some idea of maximum cost of original equipment:

Shelving and wiring.....	\$ 42.50
Apparatus and glassware.....	331.75
Media, chemicals, etc.....	36.60
Total	\$410.85

In this total is counted the cost of material and apparatus for clinical work, amounting to about \$30.00.

This equipment includes all that is necessary for preparing the usual culture media, based upon "Standard Methods" of the American Public Health Association. A careful calculation, however, shows that the dehydrated media now on the market in many cases would cost no more than that prepared in the laboratory and would save a little equipment, as well as time. This would

Fig. 3. The work bench and supply shelves.

not hold good for Loeffler's blood serum, if an abattoir were nearby.

Many economies have been practiced, such as storing media and filing cards in cigar boxes and utilizing discarded bottles from the drug stores

for solutions, while an ordinary egg incubator worked quite successfully in lieu of the electrically heated one that has now been installed (Fig. 1). A glass-door, portable baking oven, heated by one burner of an oil stove (Fig. 2) has been substituted for the usual and more expensive hot air sterilizer. An oven thermometer, such as is advertised for domestic purposes, is placed just inside the door and it has been found possible to

maintain any desired temperature indefinitely by proper manipulation of the burner. A further material saving is effected through the payment of light and water bills by the county authorities. While limitless sums can be spent upon conveniences and refinements of laboratory equipment, the amount given here will provide a workshop in which the highest grade of routine, standard work can be quite creditably performed (Fig. 3).

CAPITALIZING HEALTH KNOWLEDGE

BY E. H. LEWINSKI-CORWIN, PH.D., EXECUTIVE SECRETARY PUBLIC HEALTH COMMITTEE NEW YORK ACADEMY OF MEDICINE, NEW YORK.

HUMAN progress has traveled along a double track. In many fields the empiricist unconsciously discovered things by observation and repeated use, and proceeded accordingly, leaving the formulation of the principles to the far-distant theorist who might come after him. In other fields, the philosopher and scientist made discoveries and formulated truths and the practical man applied them to every-day life. With the exception, perhaps, of the realm of politics, the second method is rapidly superseding the first in spite of human inertia. The epoch-making discoveries of the last half century exercise a direct bearing on our mode of life, and individual as well as collective enterprise is making use of them.

Public health administration is one of the beneficiaries of scientific enterprise. Thanks to medical discovery and research, we have made tremendous strides in rendering our life environment more sanitary and wholesome. Age-long habits and prejudices are rapidly giving way before the application of exact science. To a large extent the period of empirical groping in the dark is passing. To be sure, there is a great deal yet to be known and every effort should be and is being made to clear away the mysteries which are still baffling us.

At the same time, we already know a good deal and we are endeavoring to apply this knowledge in raising the standards of public health. Our efforts, however, are only partially successful. The reason for this circumscribed success is our

Under the auspices of the New York Academy of Medicine and the Bureau of Municipal Research of New York City, an experiment has been started in New York to afford an opportunity for those engaged in public health work to come into direct contact with the leaders in the field of preventive medicine.

Rather than appropriate money for a surrey, which often is merely an exposé of the defects, and results in no definite accomplishment, it is to be hoped that communities will send their health administrators to learn the last word in the application of preventive medicine to the problems of administration.

failure to disseminate broadcast the knowledge which we do possess. There are two ways of enforcing the sanitary laws which we adopt. One is by the exercise of police power, and the other is through the enlightenment of the citizenry of the importance of obeying them. We have about reached the limit of achievement by means of the police powers with which we clothe our autocratic boards of health. Because some of the health authorities wield this power unwisely and because the bulk of the people do not fully appreciate the significance of sanitary regulations, the effectiveness of our health laws is only of a limited degree. In order that better progress in health work may be obtained, it seems essential that the scientifically established fundamentals of public health be grouped into the consciousness of the demos. In other words, we must capitalize the knowledge we possess and float it on the people. This is probably the best method by which we may hope to overcome the individual and collective indifference which blocks our efforts directed at combating disease. The ignorance on the subject, even in otherwise intelligent and well-informed persons, is astounding. The general public is still at about the same stage of health enlightenment as were the municipal authorities of one port in the South some time ago, when they required thorough disinfection of a barrel of carbolic acid before it was allowed to be landed from the vessel which had brought it to the port.

Public health education is the keynote to full success in the public health movement. The peo-

ple are naturally interested and absorb information with regard to the etiology of preventable diseases and modes of guarding against them with alacrity if it is presented in an interesting way. The success of campaigns carried on in various communities bears out the statement. The movement is well under way and has received particular stimulus during the war. It may be said that one of the permanent benefits of the war is the demonstration it gave of the large amount of physical unfitness among our young men, and the stimulus it afforded to personal hygiene and public health education. Venereal diseases, which were never before mentioned in the newspapers, are being discussed in the press and even from the pulpit. Some departments of health have gone a step further and do not speak of venereal diseases but speak of syphilis and gonorrhea in publications designed for popular consumption. It is important that this movement, so well started, should not be allowed to slacken. There are signs already in certain communities of a diminution of the public health education activities.

It is only when the city authorities fully appreciate the importance of public health education that the necessary appropriations for that purpose as well as for other public health activities are forthcoming in the proper measure. When a community, through civic interest or municipal appropriation, makes a health survey, it discovers the many ways in which it has been criminally negligent in meeting its sanitary problems. Very often such surveys made by experts result in a rectification of conditions and the voting of proper outlays for the purification of water supply, establishment of modern sewage disposal systems, the introduction of medical examination of school children, babies' milk stations, and what not. In other communities, because of the indifference of the city fathers, or because of the inability of the health officer himself to appreciate his opportunities, the deficiencies brought out by the surveys are left unremedied. The lack of understanding of the possibilities of saving human life and the conservation of vital resources on the part of the community, and the lack of interest or knowledge on the part of the authorities, are responsible for the slight progress made in so many of our rural and urban communities.

The United States Public Health Service has been doing splendid work in arousing the people to an understanding of health hazards and an appreciation of the ways and means of guarding against disease in a personal and collective way. The American Public Health Association, through its annual meetings, offers an opportunity to those engaged in public health work for an exchange of

ideas and views regarding administrative procedures. The several schools of public health connected with our universities are offering splendid courses for those who wish to equip themselves with the necessary impedimenta to carry on the work of public health administration and research. This field will become more attractive to ambitious men and women when, with the rise in public appreciation of the importance of public health, the present meager compensation allowed to health officers will be increased in accordance with its importance.

There is, accordingly, a further field for capitalizing successfully our knowledge with regard to the principles of public health administration. Those who are already in the field and who have had no opportunity of receiving a very thorough grounding in the problems of administration and who, for financial reasons, cannot afford to leave their posts of duty to take long courses in well-recognized seats of learning, are handicapped. In order to meet the needs, in an experimental way the Bureau of Municipal Research of the City of New York has organized, in cooperation with the Public Health Committee of the New York Academy of Medicine, a six weeks' course in public health administration. This course is to consist of three weeks of lecture-conferences and three weeks of field work in cooperation with the New York City Department of health. It is believed that such a course will supply practical health officers with ideas which will suggest themselves when they are placed in intimate contact with a large number of men recognized as leaders in the respective fields of sanitary science and preventive medicine. It is hoped that many communities, instead of appropriating money for surveys, will send their health officers to these conferences in order that they may, by their observations and through contact with a large number of other men, obtain sufficient knowledge of successful administrative devices to warrant the undertaking of changes in their own administrative policy which would be in conformity with those tested out successfully elsewhere.

This training course is to fill the needs of those for whom the short duration of the annual meetings of the American Public Health Association is insufficient, and those who cannot take the long courses of a university school. It is to be midway between the two. If this course proves to be a success, it will probably be initiated by other bodies in various parts of the country and will help greatly toward capitalizing our store of public health knowledge and the established principles of administration which have been worked out through years of experimentation.

THE INFLUENZA EPIDEMIC AT JEFFERSON BARRACKS, MISSOURI

BY LOUIS M. WARFIELD, (MILWAUKEE) MAJOR, M. C., U. S. A., CHIEF OF MEDICAL SERVICE, AND AMAND RAVOLD, (ST. LOUIS) MAJOR, M. C., U. S. A., CHIEF OF LABORATORY SERVICE.

THE epidemic of influenza which swept the country began in this camp on September 28. For four or five days previous to that time we had noticed that there were a few cases which were somewhat different from any cases which had previously come to the hospital, and we suspected that we were then having to do with the beginning of cases in the epidemic. However, it was not until September 28 that the first typical cases were admitted, and from then up to November 12, when the epidemic practically was over, we saw 2,054 cases. Chart 1 (Fig. 1) shows the daily admissions, the number of cases diagnosed as pneumonia, and the number of deaths from pneumonia.

Our personnel on October 4 consisted of 3,935 men. From October 5 to October 10, 5,000 men for limited service came into the post, making in all 8,935 men present in the post during the epidemic. A number of these were taken directly from the trains to the hospital, some of whom died. Chart 2 (Fig. 2) shows the number of men in the various commands who were attacked by the disease.

We were fortunate in having at hand six new pavilion wards which were just about completed and had never been occupied. These were rapidly equipped. Cantonment barracks buildings were later emptied of their men and made into hospital wards, and three of the permanent brick buildings, used by the Eighteenth, Twenty-third and Twenty-seventh Companies, were equipped for hospital purposes (Fig. 3). Each one of these buildings accommodated 120 cases (Fig. 4). The greatest number in the hospital on any one day was 1,241.

The usual precautions against cross infection were at once put into effect, and at first all gatherings among the men at the post were forbidden.

TABLE 1—MORTALITY FROM INFLUENZA AND COMPLICATIONS
This table includes the date of November 12. No deaths since November 5.

Total number of men in camp.....	8935
Total number of cases ill.....	2054
Percentage affected	23%
Cases pneumonia	368
Cases empyema	7
Deaths from pneumonia	120
Mortality of pneumonia.....	32.6%
Mortality among all affected.....	5.8%
Mortality in whole personnel.....	1.3%

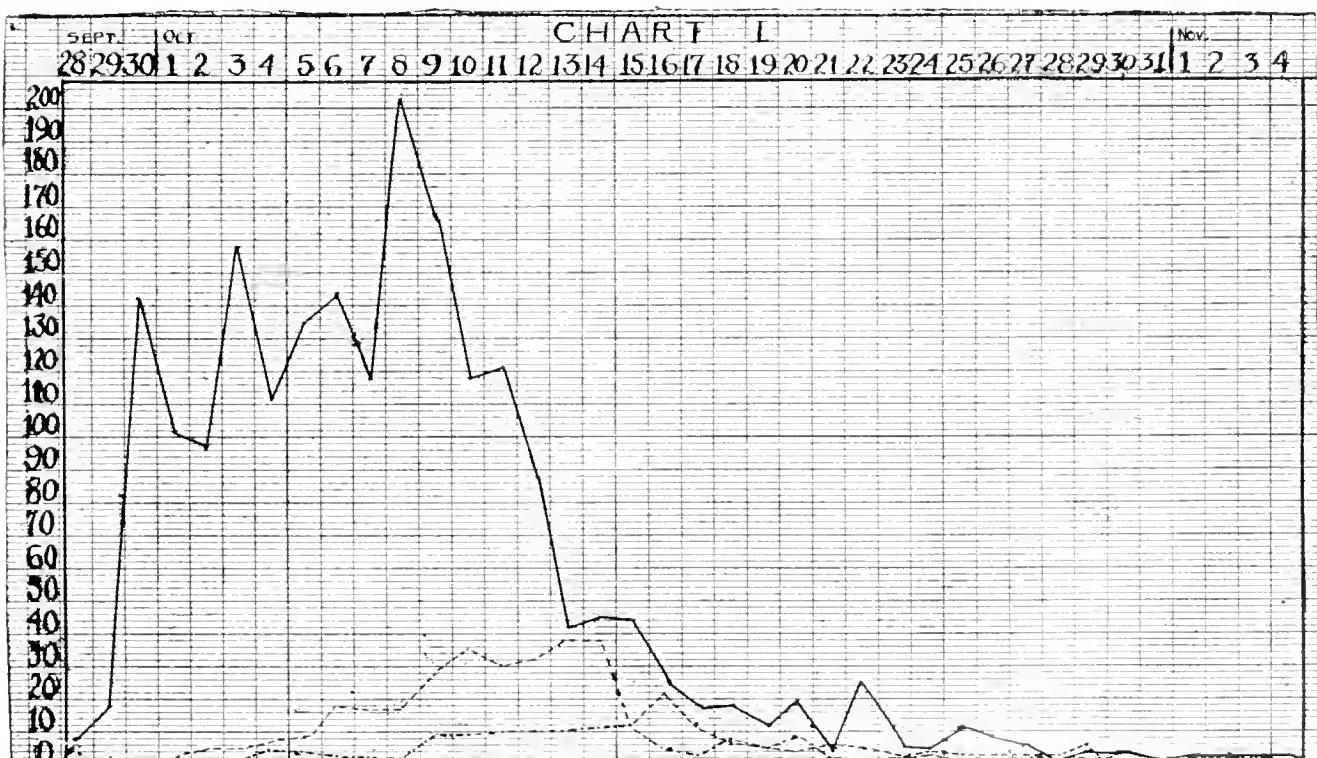

Fig. 1. Chart 1. The influenza epidemic at Jefferson Barracks, Missouri. Continuous line, daily admissions. Upper dotted line, cases of pneumonia reported daily. Lower dotted line, deaths occurring by days. No deaths after November 5.

Within two days, however, this was seen to be unwise; so the Y. M. C. A., K. of C., and post recreation halls were opened again under certain restrictions. The seating capacity was decreased by removing every alternate row of chairs, and the remaining chairs were spaced three feet apart. Guards were stationed so that the buildings were used to that limited seating capacity only. At the same time, all passes for the city of St. Louis were withdrawn, barracks were placed under strict quarantine, and all the men on the post were inspected twice daily by medical officers. By this means we were enabled to pick out, at the earliest moment, the infected, who were sent at once to the hospital. Further, all men in barracks slept in cubicles made by hanging sheets between the beds, and in tents the cots were spaced farther apart than usual. We used certain wards exclusively for influenza, and all men contracting pneumonia were transferred at once to pneumonia wards. We used for these wards our best-equipped pavilion wards with wide porches, and, so far as possible, all pneumonia patients were treated out-of-doors, the weather during the whole period being ideal (Fig. 6).

Clinical Courses of the Disease

The onset and general character of the disease differed in no sense from the cases seen elsewhere and published in recent reports. We had the same experiences as others had in seeing the rapid development of cyanosis and edema of the lungs in some of our fulminant cases. However, we saw no such cases as described by Friedlander *et al.*, of acute fatal edema without bronchopneumonia. In all our severe cases we were able to demonstrate patches of bronchopneumonia. All our deaths were due to pneumonia, some of which were of the lobar type. We fully agree with Christian in his contention that all deaths during this epidemic were due to pneumonia and not to so-called influenza. So far as our cases are concerned, there was not one who died without a diagnosis of pneumonia being made from definite physical signs. We are firmly convinced that the cases in which death is said to have occurred from influenza were those in which either pneumonia was not looked for or hasty examinations failed to detect it. There were a number of cases in which a definite pneumonic patch was discovered in the right or left lower midscapular region and which, within twenty-four hours, had completely disappeared. On the contrary, there were cases starting with a small patch which, by the following day, had developed signs in one whole lung and which rapidly terminated fatally.

The cause of death in almost all our cases, we feel, was due to intense toxemia. It would seem

to us that the heart was not at fault, as it is so often in the ordinary cases or as it was in many cases of pneumonia which occurred last winter and spring, due to the *Streptococcus hemolyticus*. We did have two cases running a prolonged course

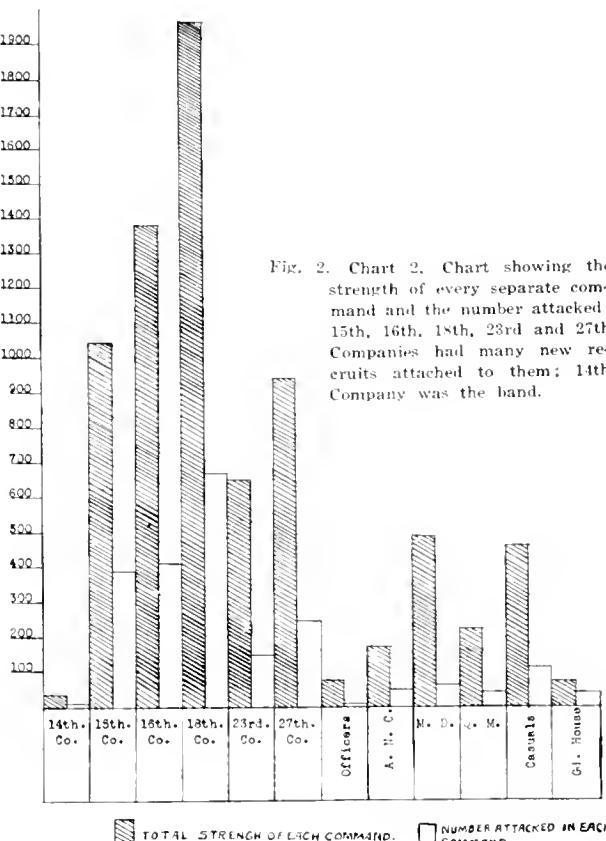

Fig. 2. Chart 2. Chart showing the strength of every separate command and the number attacked; 15th, 16th, 18th, 23rd and 27th Companies had many new recruits attached to them; 14th Company was the band.

in which it appeared that the heart muscles finally gave out. One of these at autopsy showed resolving lobar pneumonia with marked changes in the heart muscle.

Complications

There were numerous complications of a mild type, shown in Table 2. Pleurisy was very common in this epidemic, and the seven cases of empyema occurred towards the last of the epidemic. In three, the *Streptococcus non-hemolyticus* was found; in three, the pneumococcus type undetermined; and in one, a staphylococcus and pneumococcus, type undetermined, were found. The only death among these cases occurred in a man who had influenza followed by bronchopneumonia, and who, when apparently recovering, developed a typical lobar pneumonia with leukocytosis, and sudden, rapid, and painful enlargement of the spleen. This was diagnosed infarcts of the spleen. He developed empyema, was operated upon, and died. A partial autopsy showed an enlarged spleen with several recent infarcts, the largest being 6 cm. in diameter on the surface.

There was a surprisingly small number of ear and sinus complications. The nose and throat department frequently spoke of the cases of myringitis which rapidly receded under treatment or, when punctured, healed in a very short time. It was difficult to determine, in many cases, whether the pneumonia was lobar or lobular in type. We were not able to make leukocyte counts on all the cases, but enough were made to confirm observations made by others that there was no leukocytosis in the lobular type of pneumonia. However, there was the usual leukocytosis when the infecting organism was the pneumococcus and the onset of the disease corresponded more nearly to that of the ordinary pneumococcus pneumonia and the physical signs early showed involvement of a large portion of a lobe.

There were ten patients operated upon for appendicitis. These cases developed symptoms either at the beginning or during the course of influenza. Leukocyte counts showed an increase in the white cells, but in no case was real appendiceal inflammation discovered. Pneumonia developed in seven of these cases, and two patients were desperately ill. All recovered. A separate report will be made on these cases.

One unfortunate accidental death due to *Bacillus aerogenes capsulatus* has already been reported.

Infection of the Hospital Personnel

Four medical officers out of a staff of sixty, including dental officers, and twenty-seven nurses out of a personnel of one hundred and sixty-six became ill. Among the medical officers the disease was of a mild type. Of the twenty-seven nurses, twelve developed pneumonia. Five were desperately ill, but fortunately all recovered. One nurse who became ill toward the end of the epidemic developed empyema. She was operated upon and made a good recovery.

TABLE 2.—COMPLICATIONS DURING EPIDEMIC

Empyema	7
<i>Aerogenes capsulatus</i> infection.....	1
Meningitis, pneumococcus type.....	1
Diphtheria	4
Myringitis	15
Otitis media	9
Rupture, <i>rectus abdominus</i> , bilateral.....	1

Laryngitis	5
Ulceration, larynx	3
Sinusitis	2
Pericarditis	1
Nephritis	1
Infarction of left lung	1
Facial erysipelas, following influenza and pneumonia	1

Diagnosis

It was not difficult to diagnose the typical cases of influenza with the sudden onset, the curious dull appearance of the eyes, the congested mucous membranes, the aches, pains, and prostration. In general, the initial high fever rapidly declined to normal temperature within forty-eight or seventy-two hours and the cases were on the road to recovery. In others, following the initial drop, there was a sharp rise, with or without a chill or chilly sensations, peculiar cyanosis of the lips with slow pulse, often dicrotic, and no increase in respiration. Examination of many of these cases showed signs of pneumonia. In other cases, no signs of pneumonia were made out. We felt, however, that all of these cases with fever above 102 degrees lasting for four or more days, and those cases with secondary sharp febrile rise following the initial drop, had patches of broncho-

Fig. 3. One of the permanent company buildings used as hospital wards during the epidemic.

pneumonia even though they were not discovered on physical examination. Evidence that is given by x-ray plates leads us to believe that this statement is true. We made plates of a number of cases and were successful in finding small patches of apparent bronchopneumonia where there were no physical signs. In all the plates there were small areas deeply imbedded in the lungs, near the hilus, which were considered to be areas of bronchopneumonia but which gave no signs of their presence on physical examination. Plates made upon recovery of such patients lacked these irregular shadows.

Prognosis

We do not remember to have seen cases of any disease where prognosis was so uncertain and difficult. Within a few hours patients who were seemingly doing well would suddenly develop intense cyanosis and edema, and die; on the contrary, other patients with cyanosis and edema who we thought would surely not recover, did

recover. This seems to be the experience of others.

Treatment

When the epidemic first started we attempted to use a general routine treatment, giving all patients a purge and aspirin in large doses. We

Fig. 4. Type of cantonment barrack which was used as hospital ward during the epidemic.

soon gave that up. As our experience grew, it seemed to us that the most important things were fresh air and constant nursing attention with symptomatic treatment. Each patient had at least one hundred square feet of space, and constant watchfulness on the part of both ward surgeon and nurse was insisted upon. All patients had alkalies, as we felt that these drugs were of value. For the distressing cough we did not hesitate to give opiates, either by mouth or subcutaneously, using codein or morphin. We always combined atropin with morphin. When pneumonia developed we attempted to quiet the cough with morphin, given often enough to produce the desired effect. For the general stimulating effects, strychnin in doses of from 1 20 to 1 15 grain, hypodermically, was given every four hours or oftener, and, for further stimulation, caffeine-sodium-benzoate, hypodermically, in alternating doses was administered. In certain cases, we used camphor, adrenalin, and pituitrin. For the most part, these drugs were used in the desperately ill cases. In several cases of marked abdominal distention we felt that pituitrin was distinctly helpful.

The pneumonia patients so often had acetone breath that we pushed alkalies in all these cases. We also thought we had excellent results from proctoclysis with 5 per cent sodium bicarbonate and 10 per cent dextrose solution administered by the drop method one hour on and one hour off. All cases were given digestible foodstuffs throughout the course of the disease. We did not confine our diets to liquids. We used carbohydrates and fats largely, and limited the amount of pro-

teins. Patients usually received about 2,500 calories daily, some more and some less. It seemed to us that the most important single factor was immediate hospitalization of cases of influenza and absolute quiet in bed. Cases of pneumonia brought into hospital were more severe and more fatal than those developing in the hospital.

Bacteriology

A large number of smears on slides from swabbings of the throat and the nasopharynx were made and stained, according to Gram, with alkaline methylene blue, or dilute carbol-fuchsin. Gram-positive and Gram-negative diplococci and a Gram-negative diplostreptobacillus were the most constant micro-organisms found. In only six cases was the *B. influenzae* definitely identified. We discovered early that the *B. influenzae* does not stain easily and made it a rule to stain all preparations, whether direct or as a counter stain in the Gram method, with dilute carbol-fuchsin never less than fifteen minutes. Haste in staining, we feel confident, was the cause of failure to find the bacillus in the beginning of our work.

Twenty-four blood specimens were collected in sterile sodium citrate solution and plated in blood agar, smeared on blood agar plates or slants in test tubes. The *B. influenzae* was found in six cases, or 25 per cent, either alone or associated with the pneumococcus, *M. catarrhalis*, streptococcus, staphylococcus, or *B. Friedländer*. Blood, a short time after death, was taken from the basilic vein in the axilla in seven cases. *B. influ-*

Fig. 5. Main hospital building with Isolation Hospital in the background. The north wing is not shown. It is similar to the wing shown in the picture. This was used almost exclusively for surgical patients.

enzæ was found once, pneumococcus three times, and *M. catarrhalis* three times.

Autopsies were held and cultures on blood agar plates and slants made from the heart blood, lungs and spleen. *B. influenzae* was found in every case, five times in the heart blood, nine in

lungs, and eight in the spleen. An encapsulated diplococcus growing freely in blood agar with the formation of small green colonies, identified as pneumococcus Type IV, was found in eight cases, *M. catarrhalis* in four cases, streptococcus in two cases, *Staphylococcus aureus* in four cases, and a capsule-forming diplostreptobacillus, probably *B. Friedländer*, in three cases. Neither the *Streptococcus hemolyticus* nor the *viridans* was found in these studies. The greater part of the bacteriological work was done by Lieut. Newman L. S. Walsh, and the results were carefully checked by one of us. Of the autopsies five showed confluent bronchopneumonia of one or both lungs, and five frank lobar pneumonias. In the bronchopneumonia there was little or no exudate into the pleural cavity, and in two there was a small, easily detached fibrinous adhesion between the lower lobe of the right lung posteriorly and the pleura. In other cases the pleura was not involved. The lower lobe right lung was involved in one and the lower lobe left lung in two cases, and in two cases the lower lobes in both lungs were diseased. The affected lobes were of a deep, dark reddish-blue color, spotted with yellowish elevated hobnail-like subpleural patches, with bright, reddish sunken areas between and around them. There were also pearly-looking areas of emphysema scattered about the pleural surface. The lobes were hard, dense, and easily cut, but were not friable. In the acute cases, the incised surfaces were deep, dark red in color, and an abundance of dark, bloody, foamy fluid followed the knife, while in older cases pus exuded from the bronchioles dotting the bloody surface with

minated epithelium and serum. The upper lobes in all the cases were emphysematous, and in two cases emphysema extended deep in the mediastinum and up into the neck. In the lobar pneumonia cases, both lungs were involved in four cases, and the right lung alone in one. There was pleu-

Fig. 7. Interior of a barrack which has been converted into a hospital ward, showing the beds arranged in cubicles. Curtains hang between the beds.

risy with purulent effusions in two cases, and massive fibrinous adhesions between the lungs and pleura. In one of these there were very thick, almost unbreakable adhesions, the remains of a former empyema with rib resection.

The upper lobe right lung in one case was smooth, of a deep slatey color, and hard and solid as a fibroid tumor. Sections through it exposed a dark blue, almost solid, glistening surface with practically no exudate. Microscopic study of sections of all the lungs is not yet completed, but from the evidence before us we believe that in all the lobar pneumonias the disease began as bronchopneumonia, for in cross-sections of the lobes, in some places deep, dark-red, almost black, triangular areas, with the base at the periphery and the apex pointing to a blood-vessel, were found.

The spleen in all cases was enlarged, from three to at least four times normal size. Acute splenic tumor occurred in three cases.

Heart

Right ventricle was found dilated in two cases with marked degeneration of ventricle walls in one case. The muscle was soft, pinkish-red in color, and tore easily. The degeneration was found in other muscle groups, and the rectus abdominis on both sides in one case was ruptured, followed by extravasation of blood into muscles and into the abdominal walls. Endocarditis in two and endocarditis with vegetation on the valves in one case was seen. No pericarditis was found. Liver was enlarged and congested in all cases. Kidneys were very much congested with

Fig. 6. Section of group of pavilion wards with porch enclosed in glass. Screens replace the glass in summer. One of the pneumonia wards used in the epidemic.

gray blotches. Smears and stab cultures were made from the incised surfaces. Microscopic study of the stained sections showed the alveoli crowded tight with red cells, polymorphonuclear leukocytes and serum, walls of the bronchiole congested, filled with polynuclear leukocytes, desqua-

cloudy swelling of the tubules. Mediastinal and bronchial glands were much enlarged and congested, and in two cases suppuration occurred in the bronchial glands, from which the pneumococcus alone was found in plate cultures.

Addenda

After our epidemic had completely subsided we received from Washington University at St. Louis, S.A.T.C., 108 cases of influenza. The epidemic had been present in St. Louis four weeks and was then subsiding. Only a few of these patients were ill, and, except for a very few, they did not have the same characteristics as the cases in the earlier days of the epidemic. Epistaxis, so common in the early days, was infrequent, and the peculiar cyanosis of the lips was found in only three cases, which developed pneumonia. It appeared as if the characteristics had been completely changed, and the last of these cases were more like the cases of what we have known in recent years as la grippe. There were fifteen cases of pneumonia which were diagnosed by physical signs, after very careful examination, in men whose temperatures remained elevated for more than four days. Some of these cases were confirmed by x-ray plates. All recovered.

Summary

At Jefferson Barracks there were 2,054 cases of influenza among 9,200 persons. There were 368 cases of pneumonia and 120 deaths (32.6 per cent). There were seven cases which developed empyema, all occurring towards the end of the epidemic. The clinical and pathological picture varied little, if at all, from cases in other camps, or in civilian life. The mortality for the whole camp was 1.3 per cent. We found the *B. influenzae* (Pfeiffer) in all our cases at autopsy, and in 25 per cent during life. However, we do not feel that it alone was the cause of the disease. There is not enough evidence yet to establish the etiological relationship. In symbiosis with the other organisms it may be virulent enough to produce the symptoms and signs observed.

It seems more probable that the cause is some organism not yet discovered. We can confirm the finding of Hirsch of a diplococcus producing green colonies on blood agar. We feel, as he does, that this organism may have some relationship to the virulent pneumonia.

Red Cross Begins Health Campaign

In the transition from war relief to peace welfare work, the Red Cross will send between thirty and forty nurses into all parts of the United States, as Chautauqua lecturers, beginning June 1. They will try to reach those communities where need is felt for public instruction in

health and hygiene. Following the lecturers will come squads of demonstrators and other Red Cross workers who will conduct health exhibits.

PHYSICAL EXAMINATIONS IN THE DRAFT

The second annual report of the Provost Marshal General recently issued is the most complete index of the nation's vitality that has ever been prepared. It covers the physical examinations of selective service men from February 10 to November 1, 1918, to the number of 3,208,446.

The outstanding facts in this cross section of the nation's population are these:

Number Examined	3,208,446
Number Qualified	2,259,027
Number Disqualified	949,419
Placed in Group "B" (Capable of Development)	88,436
Placed in Group "C" (Capable of Some Service)	339,377
Placed in Group "D" (Capable of No Service)	521,606
Examined by Camp Surgeons.....	2,296,293
Rejected	172,000
Inducted Into Service.....	2,124,293

Reduced to percentages, we find that 25.29 per cent were rejected by local boards, and of those who went to camp 8.1 per cent were rejected by the camp surgeons either before or after induction, thus 35.3 per cent were rejected for military service.

The local boards placed 16.25 per cent in class "D" as totally unfit for any service; 10.58 per cent in class "C" as capable of rendering some service; and 2.78 per cent in class "B" as capable of correction and development. Counting those placed in class "D" by the camp surgeons, we find 21 per cent unfit for any military service whatever.

The causes for rejection:

	GROUP "D"	Total	Per Cent
Causes of Rejection		Rejected	
Heart and Blood-Vessels.....	61,142	13.07	
Bones and Joints.....	57,744	12.35	
Eyes	49,801	10.65	
Respiratory (Tuberculosis)	40,533	8.67	
Developmental Defects	39,166	8.37	
Hernia	28,268	6.04	
Mental Deficiency	24,514	5.24	
Nervous and Mental Disorders.....	23,728	5.07	
Ears	20,405	4.38	
Flat Foot	18,087	3.87	
Teeth	14,793	3.16	
Skin	12,519	2.68	
Thyroid	8,215	1.76	
Respiratory—Non-Tuberculosis	7,823	1.67	
Genito-Urinary (Non-Venereal)	6,309	1.35	
Genito-Urinary (Venereal)	6,235	1.33	
Tuberculosis (Other than Lungs).....	4,136	.88	
Digestive System	2,476	.53	
Alcohol and Drugs.....	2,007	.43	
All Others	14,314	3.06	
Cause Not Given.....	25,419	5.44	
Total all Causes.....	457,694	

Comparison of certain groups were made of those placed in class "D":

	Per Cent
Urban Regions	21.68
Rural Regions	16.89
Colored	17.32
White	16.08
Alien Communities	17.14
Native Communities	13.64

Figures of those placed in classes "D" and "C" are not given.

Statistics of the examination of men 21 years of age show a larger percentage fit for full duty than of those 21 to 30 years of age; 76.89 per cent of boys 21 years of age were fit for full duty, while only 69.17 per cent of men from 21 to 30 were declared fit for full duty by the local draft boards.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

MEDICINE AND SOCIAL WELFARE

MARKE~~D~~ changes of great significance are taking place in the field of medicine. The idea of individual responsibility for medical care is rapidly changing to one of social concern for the welfare of every unit. The changes are taking place along two lines: The organization of public health measures, broadly conceived, and the reorganization of private medical practice for more complete service. These two lines of development are rapidly converging and are already beginning to touch each other. All indications point to their early coalescence into a broad policy of medical social service.

MODERN MEDICINE is dedicated to the task of considering the coordination and efficiency of these new movements for human welfare through medical and health service. It does not seek primarily to enlarge the scientific data and knowledge of medicine and health, but rather to aid in the important function of putting the existing data and knowledge into action. It looks upon the uses of medicine not merely from the standpoint of individual need, but also from that of the group and of society as a whole. The organization of the machinery of preventive and curative medicine and of public health is the central problem with which this magazine will be concerned.

The field is an extensive and an enlarging one. It includes the organization of all forms of medical practice, the organization and administration of public health service, the scope and purposes of industrial medicine, the restoration and rehabilitation of disabled men, the medical service under workmen's compensation and health insurance, the medical care of the poor and destitute, the health supervision of schools, infant welfare, physical and health education, the training of medical and health workers, and equipment for complete medical and health service.

The Department of CURRENT PROBLEMS IN SOCIAL MEDICINE has for its field the relationship of organized medicine to social welfare and will deal with those new problems and with those new phases of old problems which an awakened social conscience has thrust upon the public attention.

Many of these problems depend upon the medical profession for solution. Social conscience tells us certain things should be done, but medical science must be called upon to tell how they may be done. It is a simple matter to prove that injured workmen should be physically rehabilitated, but medical men must supply the scientific way to do it. When it is called to our attention, malnutrition of children is deeply deplored, but medical science must be called upon to tell how the evil may be corrected.

Just because these problems are so important, and because the physician is such an important element in their solution, there comes the danger to the medical profession and the need for constructive programs. Society is not tolerant when it is unduly aroused—it tries to take short cuts to cure its ills. How to solve these social medical problems, without short cuts, is the question which we now face.

Hygiene, sanitation, health insurance, and a more widespread extension of medical service offer escape from much of the industrial unrest and discontent that unhappily exist in the great commercial centers of the modern world. Given its widest application, modern medical science has within the province of its activity and practice the power to remedy or remove a major portion of the ills that disturb the life of communities.

It is both the opportunity and the responsibility of the medical profession to lend itself to the task of removing the cause of every devitalizing drain upon the energies and health of men and women. This is the function of social medicine.—EDITOR.

BETTER HOUSING—WHAT IT ASKS OF THE PHYSICIAN

By CHARLES C. MAY, ARCHITECT, NEW YORK

IT is many a century since the first medicine-man bethought him to make his tepee somehow distinctive and, in so doing, invoked the aid of architecture in the practice of his art. Beginning therewith to dictate the structural expression of his requirements, his followers have been at it ever since, and with increased insistence as the definition of good practice has become more clear and detailed. One may rightly say that good architecture of today must be the expression of the best thought and practice in the profession which it seeks to serve. This is true in many directions, but eminently in medicine. So much have the doctors had to say to the architect.

Consider for a moment some of these dicta, and reflect whether or not the architect has been quick in his grasp of the desired end, and intelligent in his understanding of the means to attain the translation of it into terms of structure. Hospital construction stands out instantly as the example *par excellence*. The doctors have been learning in their laboratories more and more of the means by which disease is transmitted; they have been able to put their fingers upon one after another of the danger spots, and to call for their elimination. The architects have listened to the word; they have kept full step with the procession. If better methods of asepsis have revolutionized surgery, and improved practice in physical diagnosis has transformed medical service within a hundred years, so, no less truly, has been transformed the architecture which translates knowledge into form. If any doubt exists on the point, it may be speedily dispelled by a study of hospital plans—the earlier with the most modern, the thick, clubby, congested, airless type of building compared with the open, wide spaced sun-lighted and cross-ventilated pavilions, the closely articulated administrative units of the best of the modern plants. Not only are buildings of the latter sort to be found, but they have become stand-

THE ANSWER OF LLOYD-GEORGE

I solemnly warn my fellow-countrymen that you cannot maintain an A-1 empire with a C-3 population. . . . You cannot bring up healthy people in unhealthy homes.

We have had acts into hundreds and hundreds of sections. We have had regulations that would fill a library. We have had the most attractive pictures of model dwellings and endless authorities. But you cannot plough the waste land with forms; you cannot sweep away slums with paper; and you cannot cope with the wants of the people with red tape.

lowed simplicity to become austerity; absence of fussy detail has sometimes meant barrenness; and the hard, easily cleaned wall surface has too often been interpreted in terms of glaring white. So the time came when the thing must be humanized again, a reaction due as much perhaps to the architect as to the doctor, for where the physician speaks in terms of psychotherapy, the architect says, "The glare of that white wall hurts me every time I look at it; and if it hurts me, I'm mighty sure it doesn't do your patients any good." So the trend of architectural expression takes a turn in the direction of warmth and kindliness and the patient is led by his surroundings to feel that not only his bone structure and his alimentary canal, but also his nervous system, and his feelings, are objects of consideration to the medical staff.

Similarly, the architecture of the tuberculosis hospital reflects the trend of modern treatment—perhaps more obviously and directly than in other lines of building. "Give them light and air," says the doctor, and at once there is produced a new type of building in which the proportion of void to solid, the areas of porch, terrace and open, sheltered spaces as compared with the strictly enclosed areas, are quite reversed from old time practice.

Along other lines, too, the association of the doctor with the architect has worked for the good of humanity. Not to elaborate, but merely to name a few of these instances, we may say that factory and industrial architecture of every de-

scription, modern "daylight engineering," all the precautions for the elimination of dust and for cleaning out injurious fumes and acids, the latest tenement house laws aimed against the evils of congestion, and all such devices and restrictions are instances of the intimate collaboration of physician and architect.

Let us admit, for the moment, that they are the outcome of what the doctor has had to say to the architect. At the moment, we believe that the architect wants to say something to the doctor. To be sure it is to ask for more instructions, but the point is that the architect sees the vision and must have the foundation of sound data from the doctor upon which to build.

The medical world has long concerned itself with the cure of disease, the rehabilitation of broken-down organs. It is now passing on, and reaching out to a far finer thing, preventive medicine. Now, if good practice in curative medicine is expressed in the best of our modern hospitals and sanatoriums, what is or will be the architectural scheme of preventive medicine?

We have made beginnings in many directions, some of which we have already touched upon. Architectural study which brings daylight into factories, which finds means to eliminate gases, fumes, dust or acids—is not this a contribution toward the ideals of preventive medicine? So with the modern school and the tenement house—could the stringent restrictions governing those types of building be enforced, were we not convinced that the generations following will make a better showing physically than does our own? We are certain that fine cattle are bred in modern, model, farm buildings—it does not occur to us to look for them in tumble-down, dark, cow sheds. We should be inclined to resentment if it were suggested that we take better care of our cattle than of our children, yet the point is debatable. Are we not justified in saying that one of the directions in which preventive medicine will express itself through the agency of the architect, will be in the greater thought and care which will be devoted to the housing of the great masses of population which thus far are admittedly neglected? In this the housing of industrial workers holds a large part, and it is just here that the architects may invoke the aid of the physicians.

No doctor needs to have the arguments for light and air, for thorough ventilation, for adequate room sizes, and all the rest of it, rehearsed before him. Yet those arguments, when brought to bear upon employers as reasons for entering the industrial housing field, are not sufficient. "Very true," says the factory owner, "but my job is

turning out buttons, not building houses." And until he can be shown that good housing for his employees will enable him to turn out more buttons per day or the same number at a lower cost, he will rarely be interested.

It might help if he could be shown a fair return on his investment, through building good houses and charging moderate rentals. Unfortunately, it is not possible so to appeal to him. The definite financial returns have repeatedly proved too small to appeal to the industrial magnate. Furthermore, the cases where industrial housing programs have been pushed regardless of the financial aspect—where the owners have set out to build, knowing full well that the investment was not economically sound—such cases do not solve our problem; they are, because of the savor of dilettante philanthropy, a detriment rather an aid.

If, then, we cannot appeal for better industrial housing on the ground of direct return, if we do not care to urge it as a philanthropy, where are we to turn for our argument? If the immediate, direct returns are inadequate, how about the slower, indirect returns?

No one who has given thought to the matter questions that there are such returns; that if they are somewhat slower to appear, they are correspondingly more stable; that if they are difficult to appraise, their value is none the less vital. The first of these indirect returns is in the lessened labor turnover in a well-housed community of workers. The exorbitant charges for "hiring and firing" which almost every business has been obliged to shoulder, have become intolerable during the hectic conditions of war production. What was formerly a subject of discussion only within the organization has now become a topic for street corner argument, for dinner-table conversation, and for congressional oratory. Organizations which have been studying the matter for years find many elements affecting for good or evil this load which hangs, a dead, non-productive weight upon their business. But while they emphasize the importance of working conditions in the factory, of the personality of shop foremen, and a half dozen other things, they are agreed that one of the most vital elements is housing—the kind of homes the workers have to live in. Given two factories with identical conditions in all other respects, but one housing its workers well, the other permitting the old style "settlement" to exist—it needs no argument to prove which of the two factories will have the greater charge for labor turnover.

For a long time the writer has been looking for some authoritative figures by which the influence

of housing upon labor turnover could be intelligently traced. For the crux of the matter is right here. Lacking the argument based on direct returns, and being forced to appeal to owners on the ground of indirect returns, it becomes essential that we somehow make tangible the intangible—that we calculate the incalculable, weigh the imponderable. As to labor turnover, detailed investigation has been proceeding for long, with results which approach those we need. The difficulty, of course, lies in segregating the single element of housing from the others. For example, we hear that the Blank Co., with poor housing, has a labor turnover of 20 per cent per month, while the Dash Co., with good housing has only half its neighbor's burden, but here, as in the great majority of such statistics, we cannot point with pride to the figures, and say, "See here what good housing does for labor turnover." For the fact is that until this has been segregated from the other elements affecting the result, the figures are worthless for our purpose. One way to accomplish this separation would be to keep records on labor turnover in some company before and after a housing program had been put through, taking precautions meanwhile to keep all other factors as nearly as possible constant. Results gained in this way over a period of years might be quoted without apology, and with reasonable accuracy.

But if the influence of housing upon so definite and measurable a thing as labor turnover is difficult to figure, what are we to say of the other features which are classed as indirect returns which the employer may reap from improved housing for his workers? With what scales can we weigh the workman's improved reliability, his increased initiative, his more healthy spirit? How measure morale? It is here that ordinary forms of investigation fall utterly short, and at this point we have heretofore found ourselves helpless. But to-day physicians are finding methods for measuring with a large degree of scientific accuracy those things which we have felt could be described but never placed in the scales and weighed. So that presently it may become a commonplace of conversation—not to say roughly, "He is a stupid fellow"—but to say scientifically, "His is a Grade B intelligence," just as we now speak of Grade B porcelain kitchen sink.

Seriously, it would seem that the modern medical profession has here an opportunity to present the whole matter of industrial housing to the employer in a new light. If we can show him that good housing will be a chief factor in raising his labor force from a lower grade intelligence to the one next higher, he will then show interest in

our pleas for properly planned industrial towns with high standard houses for the workers. England has made a beginning along these lines, though principally based thus far on the physical rather than the mental aspects of the case. The following statements from Mr. George Cadbury's book on city planning have grown familiar through wide quotation, but are distinctly apropos:

	Infantile Death Rate per 1,000 Births	Ordinary Death Rate per 1,000 Births
Bourneville	55.0	4.8
Letchworth	50.6	6.1
Hampstead	62.0	9.8
London	101.0	13.6

Persuasive are the statistics, also given, of the effect on boys and girls, in weight and height, of the conditions of a garden town like Bourneville, as compared with Saint Bartholomew's Ward, in Birmingham, only twenty minutes away.

	Age 6 yrs. Weight lbs.	Age 8 yrs. lbs.	Age 10 yrs. lbs.	Age 12 yrs. lbs.
Boys, Bourneville	45.0	52.9	61.6	71.8
Boys, St. Bartholomew's Ward..	39.0	47.8	56.1	63.2
Girls, Bourneville	43.5	50.3	62.1	74.7
Girls, St. Bartholomew's Ward..	39.4	45.6	53.9	65.7

	Heights in.	in.	in.	in.
Boys, Bourneville	44.1	48.3	51.9	54.8
Boys, St. Bartholomew's Ward..	41.9	46.2	49.6	52.3
Girls, Bourneville	44.2	48.6	52.1	56.0
Girls, St. Bartholomew's Ward..	41.7	44.8	48.1	53.1

Take these two groups of boys and girls, one hundred from the city slum, the other hundred from the garden town, and line them up before your industrial magnate. "There you are, sir, from which group will you recruit your shop forces?" Is there a question as to where his choice will light? And as soon as he has made his obvious choice, the argument is given over into our hands. If these youths from the well-housed town are more robust, better developed, keener in intellect than the slum-grown product, then they are worth more to the employer. And if they are worth more, he can be shown his self-interest, his duty to make a contribution from his business account toward producing such a crop of human material.

Some such program of investigation, it seems to me, is the proper line of approach to the employer of labor, who is doing nothing for his employees' home conditions, but who ought to be. Perhaps there are statistics of the sort we have described, now available in this country. If so, they have not been given proper exposure to the light, for many of those most vitally interested have never seen them. If not, then, can we appeal to the medical profession to provide us with the ammunition we architects need for the campaign? The idea is here no more than hinted at; the physician will know how to take hold of it and apply it to good purpose.

THE IMPORTANCE OF CHILD HYGIENE IN NATIONAL RECONSTRUCTION

BY RICHARD M. SMITH, M.D., BOSTON, MASS.

THE war has made it apparent that there must be a readjustment of our national life. No factor is of greater importance in this reconstruction than the proper care and protection of the rising generation. Interest in children has been quickened everywhere by the experiences of the last few years. Public health authorities of the nation and of the states are exerting renewed efforts for the conservation of child life, and private organizations throughout the country are increasing their efforts in the same direction.

A complete conception of child hygiene must include the various stages of a child's development and its varied activities. A child's life may be divided into four periods: (1) prenatal, (2) infancy, (3) pre-school age, and (4) school age.

At the outset the basic importance of economic factors must be considered. Unless efforts are exerted to improve the housing conditions, to increase wages, and to secure healthy parents, much of the energy expended directly on the children will be wasted. These broader and less definite considerations have so direct a bearing on the question that they cannot be neglected.

For the most effective work in child hygiene two forces are necessary—public officials and private agencies. It is imperative that the closest cooperation exist between the two; each must be appreciative of the work being done by the other. Public health authorities of necessity are conservative and carry on their work under limited financial support and in the face of many conflicting interests. Private agencies can do much more extensive and intensive work. They should support loyally all that the public officials are doing well and supplement with their own workers what the public officials cannot do. They must also provide an adequate community backing for the public work and sometimes also inspire the public officials to do that which they have not yet under-

THE NATION'S DUTY TO THE CHILD

This great war was fought, and won, for the sake of the children—the men and women of to-morrow.

It is our duty to the child to assure the best possible physical and economic surroundings, to furnish proper food, to secure protection from disease, and to provide every means for growth and development of a healthy and perfect body.

No factor is of greater importance in this reconstruction than the proper care and protection of the rising generation.

taken. The two forces together must educate the public, and sometimes even the physician, to the full realization of what can be accomplished.

Prenatal Care

The importance of prenatal care, which in reality is maternal care, has been emphasized again by experiences during the war. To improve the health of the children it is necessary to maintain the health

of the mothers. The mother should be provided during her nine months of pregnancy with proper food; her living conditions should be adequate; her personal hygiene should be carefully regulated; and she should be protected from the necessity of working up to the time of confinement or of returning to work soon after. She should have proper medical attention during this period. At the time of confinement she should receive adequate obstetrical and nursing service, and hospital care if necessary. In many communities, especially in the rural sections of the country, proper medical care is hard to obtain, and in these places midwives often are in practice. Whatever one's attitude may be with reference to the desirability of licensing midwives, one must recognize that the midwife exists and that, if she is to be done away with, some substitute must be provided. If the midwife is to be continued as a recognized part of our medical equipment, there must be some means for her proper training and supervision.

Infant Welfare

Interest in infants has been widespread for many years. Despite this interest and despite the reduction of infant mortality in many parts of the country, large numbers of infants die needlessly during their first year of life. A newborn infant has less likelihood of living a year than a man of eighty.

Prenatal and natal conditions cause the great-

est proportion of deaths during the first year. Adequate maternal care during pregnancy and in labor will prevent most of these deaths. Digestive disturbances cause about one-quarter of the infant deaths. Improving the milk supply has contributed greatly in certain communities toward reducing the deaths from this cause, but much more can be done in many parts of the country in this particular. Recent knowledge of metabolism and of intestinal diseases as applied to infants has resulted in better feeding of babies. The most important advance is the renewed and increasing interest in breast feeding. It is now generally recognized that breast feeding is the greatest safeguard for the lives of infants.

In this connection it is important to bear in mind that all our statistics depend for their value upon adequate and accurate birth registration. A baby has a right to be registered at birth. There are reasons for this, aside from the interest in statistics. The recent draft has illustrated one and many others exist.

It is also important to recognize in this connection that the time has come when some action must be taken in regard to illegitimacy. The child born of unmarried parents has a right to a different status in the community from that which he has occupied heretofore. He must not be made to suffer as the result of circumstances for which he was in no way to blame.

The Pre-school Period

Until within the last few years very little attention has been given to the child between the ages of one and five years. It is now recognized that this is an extremely important period of the child's life. The number of deaths during this period is much less than during the first year, roughly, about one-third as many, but many physical defects make their appearance during these years. The recent draft has emphasized the importance of these defects.

The diseases of the respiratory tract and the contagious diseases account for most of the deaths. Progress in the prevention and treatment of respiratory diseases has been extremely slow. The problem is not different from that of adult life, but the deaths from these diseases are more numerous in the period under consideration than in later years. Therefore, the importance of study in this field is correspondingly greater. The contagious diseases occur very frequently and the deaths from diphtheria, despite antitoxin, still comprise the largest single group.

The defects occurring at this time are dependent upon growth. The food changes from milk to a varied diet. It is important that this transi-

tion should be accomplished without digestive disturbances and also that it should be made in proper fashion to provide for the needs of the growing body. As a result of improper feeding anemia and the deformities of rickets appear, and postural changes, particularly round shoulders, prominent abdomen and flat-foot, develop. Enlarged adenoids and carious teeth are so common as to be taken almost as a matter of course, but failure in normal development because of them may result in permanent physical handicap. If proper attention is given to food, posture, teeth and adenoids, most of the deformities of early childhood will be prevented and men of twenty will not be turned down for military service in such large proportion as was the case during the last draft.

Many infants and young children because of the economic condition of their parents are put in day nurseries. Day nurseries are not desirable, but they exist and will continue to exist for many years. Some provision should be made in every state and city for standardizing these nurseries and for providing adequate medical supervision. Children forced to spend their days in these places should not be exposed to disease and should be provided with air, light, and proper food.

The mental development of children is very active during the first five years. Recognition must be made of the fact that the habits established, whether good or bad, are the habits which last through life. Many of these habits affect health. Eating habits and sleeping habits may be cited as illustrations, but many others apparently less intimately connected with bodily development are nevertheless important. These habits must be formed correctly if the child is to be truly healthy.

School Supervision

School nursing has long been embodied in the public educational system. It is well known that 75 per cent of the school children in the United States have some form of physical defect detrimental to health. Most of the defects are remediable. We know that from ten to fifteen million school children have carious teeth and that about one-third as many have varying degrees of malnutrition. The great need at the present time is not a further collection of statistics, but an active campaign to provide means to remedy the defects which are known to exist. We must secure adequate dental care for school children. In many rural communities this will necessitate a traveling dentist, who will go from place to place or school to school, doing all the work that needs to be done in each place and then moving on to the next. We must also do something to cure the malnutrition

already existing and to prevent its developing in the next generation of school children.

The so-called "contagious diseases" cause the greatest number of deaths in this period of life. Further means must be devised to insure the detection of these diseases among school children and to secure their control.

The children themselves should receive definite instruction in personal hygiene and the methods of keeping well.

The Child in Industry

No discussion of child hygiene would be complete without mention of the necessity of interest in the child in industry. The Federal child labor law was unfortunately declared by the Supreme Court to be unconstitutional, but new efforts are being made to secure legislation to pro-

tect children from improper labor. The war has given great temptation for relaxing existing standards, but now that the war is over, there must be no lowering of the bars. The older children, who may work legitimately, must be surrounded by the proper safeguards for health.

The war has removed many of this generation even in this country and many more in other countries. Everywhere there is a deeper realization of the necessity of doing everything possible for the next generation. This great war was fought and won for the sake of the children—the men and women of to-morrow. It is our duty to the child to assure the best possible physical and economic surroundings, to furnish proper food, to secure protection from disease, and to provide every means for growth and development of a healthy and perfect body.

THE BIOLOGICAL SIGNIFICANCE OF PHYSICAL EDUCATION

BY R. TAIT MCKENZIE, M.D., LATE MAJOR, R.A.M.C., DIRECTOR OF PHYSICAL EDUCATION, UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA, PA.

FOR the last year, two million of our young men have been under regular physical training of the most strenuous kind, but in the preliminary examination for the draft an additional third had to be rejected for physical defects, many of them due to lack of normal physical development. It is peculiarly appropriate then, at this time to understand how fundamental is that contribution made by exercise to a sound physique.

The growth and development of a child is directed by the play instinct, an automatic system of physical education based on spontaneous exercises of his own devising, and the amount of muscular work done by an infant is quite as great as that done by an active adult, weight for weight. The infant kicks and squirms, waves his arms and legs continually when awake, but almost the only coordinations that are developed at birth are those of sucking and grasping, intimately associated with his survival. The importance of giving free play to all his movements and the danger of preventing them by tight and confining clothing seems self-evident, although it is often neglected. He progresses to the more accurate coordinations of picking up and throwing objects, pulling things apart, building up blocks, and, finally to balancing himself in the upright position, which is man's greatest muscular feat.

Roughly speaking, the first seven years of in-

cessant activity are devoted to testing everything within reach, in this world with which he is surrounded. He makes experiments in the resistance of the walls and steps against which he bumps his head; in the weight of the blocks which he drops on his foot; and in the use of simple tools.

At about seven years, a new ambition shows itself, and he evinces a desire to test himself against his fellows in speed, strength, and agility. He feels the need of a moving target, and so all the games of tag appear, under their various names: hide and seek, prisoner's base, and duck on a rock. In these he gains an entirely new set of experiences, and is able to determine his relative position among his fellows.

It is not until he attains the age of twelve that he begins to recognize that he is only a part of an organized unit, and his games reflect this new knowledge, showing the development of the spirit which subordinates the individual to the group, and although the activities of the first period continue throughout his whole growing life, increasing his mastery over the powers of nature in such exercises as rowing, swimming, climbing, hunting, gardening, and while the personal competition that he learns in the second period is continued in the more formal sports of boxing, wrestling, and fencing, the contribution of the period from twelve years on is almost purely a social one. It

is the "gang instinct" seen in team games like baseball, hockey, basketball, and football. All these sports, worked out to their complicated organization by the children themselves, have their fundamental value in developing the body harmoniously and training the individual in the use of all his physical and mental powers.

As he grows older, the more violent of these games are replaced by others, requiring a closer coordination and more advanced development of the reasoning powers. There is no hygienic reason why a boy of twelve should not take up a game like golf or fencing, but, as a matter of fact, few boys will choose games requiring such *finesse*. The enjoyment and appreciation of them comes with the increased development of the more intellectual faculties, while the more violent tests of endurance and strength become more and more distasteful as age increases. Under natural conditions, these games develop into occupations in which the boy uses his manual skill. The natural occupations like farming, fishing, lumbering, and the various crafts require a sufficient amount of muscular exercise, mostly in the open air, but even they tend to specialize, and in America the proportion of town dwellers has gone up to nearly 60 per cent of the total population. The artificial and confining conditions of industrial and city life must be faced. There is not enough space and air for each individual to develop normally, if he is left to himself.

In our industrial life, machinery is designed wherever possible to reduce muscular activity to a minimum. Even the child is kept for hours in more or less restrained positions in school. Everything tends to suppress muscular activity, or to limit it to a few automatic movements, and artificial remedies must be taken for this artificial condition. Lieutenant Farré, the French aviator, on being asked what impressed him most about the American people, said, "Your sports seem to me the result of the way in which you make machinery do all your manual work." Roof gardens, recreation piers, playgrounds and other breathing spaces are not a luxury, they are a vital necessity. The skilled direction of them to get the greatest possible amount of recreation and exercise for the children has produced a class of teachers whose employment is imperative for our national development. The sending of city children out into summer camps and organizations like the Boy Scouts, which teach woodcraft, and the Playgrounds Association, which provides playgrounds, are not fads, but investments to raise the level of physical manhood and womanhood.

The college man or woman is now fairly well provided for physically in most well-organized

colleges and universities, although there is always a tendency to expend the energies on those who need it least and to avoid the ungrateful and difficult task of applying it to those who need it most and who, in many cases, do not realize this fact. The danger point in most men comes when they have left college and have plunged into active business or professional life. The tendency to under-exercise and over-eat means they use up their physical capital until impending bankruptcy sooner or later brings them into the hands of the physician. Communication by mail and by telephone doubles or triples the amount of business done by most men, but it also exacts an additional toll of nervous expenditure, and there is little wonder that so many men are unable to keep up the pace set for themselves at the beginning of their business career. These are the men and women to whom the correspondence schools of physical culture are most alluring, with their promise of incredible results from the modest expenditure of a few minutes daily, while the secrecy with which they are shrouded and the high price they demand for instruction add not a little to their attractions. Such men would benefit from any exercise vigorous enough to stimulate the circulation and the skin. These tabloid systems are composed usually of simple exercises and, to be of any value to the sedentary worker, they must emphasize the use of the muscles of the trunk and of the arms, which are habitually slighted by the work of most men and women. Lists of such exercises have been compiled and published by such men as Luther Gulick, J. P. Muller, and Walter Camp, sometimes under the ambitious title of "systems," but the best collection I know of is that of William J. Cromie, entitled "Fifteen Minutes Invested Daily for Health."

A quarter of an hour of intense muscular action, involving the great muscle masses of the legs, trunk, and shoulders, stimulates the heart and draws the circulation out into the extremities, and causes profuse perspiration. When followed by a shower and rub down, the feeling of exhilaration is unmistakable, but a word of warning is necessary to those whose constitutions have lost the resilience of youth. They may easily suffer from overstrain.

Some of the more mechanical and unnatural exercises have another disadvantage, which, although less serious to the health, sometimes puzzles the victim. They put the golfer off his drive, and the tennis player off his stroke. Natural games cultivate certain coordinations that work smoothly only after long practice, and these quick systems throw a monkey wrench into the delicate machinery of a smooth and accurate long drive

in golf. At best, they are makeshifts, for nothing will take the place of long hours in the open air, however the time may be occupied, whether in golf, walking, climbing, canoeing, rowing, gardening, or hunting.

No age can be slighted if the national vitality is to be kept up and improved, but the growing

period is, of course, the most important, and the laws that are already in force or are now before the state legislature for making physical education a part of the school curriculum, show that the public consciousness is now aroused, and merit the support of every citizen who has the highest welfare of the American people at heart.

DENTISTRY AND HEALTH CONSERVATION

BY HARVEY J. BURKHART, D.D.S., DIRECTOR ROCHESTER DENTAL DISPENSARY, ROCHESTER, N. Y.

IT is only within a very few years that any considerable number of people have appreciated the value of clean mouths and good teeth. The services of a dentist were sought for the purpose of bringing relief in acute toothache, the repair of broken teeth, or providing artificial substitutes. Not many people have visited a dentist because of an appreciation of the fact that the mouth is a breeding place for many different germs of disease, and therefore should be kept in a hygienic condition. A woeful ignorance exists even today of the far-reaching effect upon the general health of pathological conditions about the mouth. Medical examiners for life insurance companies, industrial establishments, etc., pay particular attention to unusual conditions in every part of the body except the mouth. Small boils and pimples are usually scrutinized with great care to determine if there is any condition which might make the applicant a poor risk. There may be a dozen foci of infection in the mouth, pouring their poisonous germs into the blood stream and the stomach, but little, if any, attention is paid to these.

The lack of recognition of dental lesions is not confined to the laity. The medical profession itself has been slow to realize the importance of proper mouth conditions. There has often been an antagonism between physicians and dentists, and the patient has been made to suffer on account of a lack of reasonable cooperation, but

happily these conditions are fast passing away. Medical men now realize that many cases of chronic diseases, acute diseases and special local diseases come from mouth infection; for example, neuritis, sciatica, acute paralysis, etc. Ulcerated stomach, diseases of the gall-bladder, appendicitis, etc., are often caused by local infections. Cases might be cited of rheumatism, neuritis, arthritis, chronic valvular disease of the heart and many others that have been greatly relieved or cured by proper dental attention.

Bacteria may enter the body in various ways, but the most common portal is the mouth. There are many places about the mouth to harbor germs of infection—carious cavities in the teeth, pyorrhea pockets, abscesses about the roots of the teeth, the tonsils, etc. That disease germs found in the mouth are a prolific source of disturbance in other parts of the body has been conclusively proved by investigations made by Rosenow and other eminent authorities, who have been able to produce, with bacteria cultures from man, similar diseases in animals. Eminent medical practitioners and health authorities are alive to the fact that mouth sanitation offers a prompt and permanent cure for many of the ills of the body.

The x-ray has been of very great value in the diagnosis of many conditions to be found about the mouth and particularly about the roots of the teeth. Medical men have for some time recog-

Rochester (N. Y.) Dental Dispensary. Founded by George Eastman.

nized the fact that many disturbances in remote parts of the body have been caused by infected teeth, and that the removal of the cause has resulted in a speedy restoration to normal health; but correction of dental disturbances has not always been a cure for every other ill. Much harm has come from the insistence by the medical man upon the extraction of all teeth showing a rarefied area in the picture. At the same time considerable damage has been done by dentists in an unreasonable insistence upon saving every tooth. Medical and dental practitioners will in the end accomplish far greater results and will be rendering a much more valuable service to their patients, if, instead of a blind insistence upon their individual opinions, they will cooperate with each other more cordially and decide upon operative procedures only after reading and interpreting the picture in connection with the history of each case, thus avoiding much needless and ruthless extraction of useful and valuable teeth. It goes without saying that any competent dentist will give the patient the benefit of the doubt rather than insist upon the retention of a tooth that is a menace to health. Equally so, the medical man should realize the importance of retaining healthy teeth for the purpose for which they are intended.

There are many well-authenticated cases of a complete restoration to health and normal function of people suffering from insanity and various nervous disorders, in many cases caused by nerve pressure from unerupted and impacted teeth. It is also well known that many cures, particularly in rheumatism and neuritis, are effected by removing sources of infection about the mouth and teeth.

A long step ahead was taken by the Government when provision was made to appoint dentists members of local draft and advisory boards, and in formulating regulations with reference to the teeth. The Government recognizes the value of good teeth and clean mouths, by requiring dental inspection, ordering the correction of various troubles about the mouth, restorations of various kinds, the supplying of artificial substitutes where necessary and the furnishing of tooth brushes.

The making of an army of over 4,000,000 men dentally fit has been a tremendous task, but it has been done. The soldiers have been made comfortable and fit by the removal of impacted teeth, the treatment of abscesses and diseased teeth and gums, the filling of cavities and the removal of various other pathological conditions. While many of these things will be only temporary in character, by far the greatest permanent good will come from the knowledge that has for the

first time been brought to many of them that a clean, comfortable and healthy mouth is essential to good health and promotes greater efficiency. The value of education to secure improved dental conditions in the army does not stop there. When the boys return to their families, they will tell them of the need for paying careful attention to their mouths and teeth, as one of the most important things to be done to maintain good health. The Government has not only provided the machinery to take care of the present emergency, but it has inaugurated an educational campaign that will be far-reaching in its effect in promoting good health.

During this war, not only the Government but various philanthropic organizations have instructed the large majority of the soldiers and sailors in hygiene and sanitation and the value of health conservation, as the same number could not have been taught in any other manner in many years to come. They have been required to keep themselves and everything with which they have had to do in as sanitary a condition as possible, because it is good business so far as the Government is concerned. These lessons will appeal to many of them as being most valuable after the war, and many communities will wake up and find soldier sanitary officers among their citizens. This is the time to inaugurate a general health campaign. This war has strikingly proved the laxity not only of the health laws but of the educational as well by disclosing the thousands who were inducted into the army who could not sign their names. Hand in hand with business reconstruction should go the reconstruction of the health laws to make healthier and better citizens. The campaign to save babies has resulted in much good, and, while there have been great advances by medical men along this line, not so much has been done to prolong adult life. This country is face to face with an industrial situation that will tax the brains of the wisest to bring about a right solution. Europe will no longer furnish the common labor for this country and we will be obliged to furnish our own. The accident and sick loss in this country may be cut in half by improving housing, sanitary, hygiene and food conditions.

In 1916 there were enrolled in the schools of the state of New York 1,962,946 pupils. In the United States there was a total enrollment of 23,209,029. The per capital cost was \$39.37 for the education of each child—a total of \$914,804,171.00. Educational authorities are alive to the value of anything that will improve health conditions, and thereby not only increase the efficiency of the child but also reduce the cost of education, by shortening the time in school. The item for

caring for the backward child and the repeater, due to the loss of time on account of toothache and diseases caused by bad mouth conditions, would represent an enormous sum in money loss for schooling. The loss to parents, who are deprived of the services of older children for these reasons, would also represent a large sum.

The economic phase of this question, the permanent good that may come to future generations by the education of children from early childhood to the value and necessity of proper attention to their teeth and health conservation, were thoughts uppermost in the mind of Mr. George Eastman, of Rochester, N. Y., when he founded and endowed the Rochester Dental Dispensary.

The Rochester Dental Dispensary was erected and equipped by Mr. Eastman, at a cost of approximately \$400,000, and an endowment of \$750,000 has been provided by him. Conditional upon the making of this gift were the requirements that twelve of the leading business men of the city should become interested in the institution, by serving upon the board of management and contributing each \$1,000 a year for five years, and that the City of Rochester should agree to appropriate the sum of \$20,000 a year for five years to pay for the cleaning of the teeth of the children in the schools and orphan asylums. Both of these conditions were at once met. It is to be noted that the appropriation on the part of the city for the prophylactic work did not make the city a partner in the conduct of the affairs of the dispensary. The dispensary is managed absolutely by the board of directors, and at no time in the future will the municipality of the City of Rochester have a voice in its management. Mr. Eastman saw to it that never in the future would any of its activities be changed or interfered with by the various political and other changes that occur in the administration of city affairs. The cleaning of the teeth of the children in the schools is and should be a general charge upon the municipality, and it was an appreciation of the value of this work in the coordination of the various activities of the dispensary that induced Mr. Eastman to require that the city should do its part, before he agreed to establish the dispensary.

The building is located not far from the business center and is convenient of access from all parts of the city by car lines. It is a beautiful, simple structure and contains the most modern dental and hospital equipment that could be obtained. Provision has been made for sixty-three dental operating units, and the hospital is furnished with every facility and convenience for nose and throat work. This institution was not established for the purpose of doing ordinary den-

tal relief and repair work. The fundamental thought was so to coordinate all of its activities that something might be worked out to prove the value of preventive dentistry. I have no hesitation in saying that while much good can be done and great suffering relieved by repair and relief work for adults, the work is of little value in determining what would be the proper methods of

Children's waiting room, Rochester dental dispensary.

treatment for children. An age limit of sixteen years has therefore been established.

It is planned through the education of mothers to have them bring their babies to the dispensary as soon as the first tooth erupts, and by follow-up methods to retain the child as a patient until the age of sixteen, believing that by this scheme opportunities for experimentation and study will be given that could not be obtained in any other way and that will finally result in the standardization of filling materials and methods of procedure that will be of tremendous benefit to coming generations. The retention in good condition of the baby teeth until such time as they are forced out by the second set exerts a most beneficial influence upon the permanent teeth. The child who is educated to care for his teeth until the age of sixteen can be depended upon to do so later and, barring unusual conditions, with a continuance of proper attention to mouth hygiene, will require little subsequent dental attention. The department of orthodontia for straightening crooked teeth is one of the important departments in the dispensary. Not only will the appearance and comfort of the child be greatly improved, but there

will result an improvement in speech by widening the arch, and not infrequently have children below normal mentality been greatly helped by the removal of nerve pressure usually found in a crowded jaw.

The removal of tonsils and adenoids and the operation for cleft palate and harelip will be most important departments of the institution. All of

The dental operating infirmary of the Rochester Dispensary.

these abnormal troubles of childhood will receive the most expert medical and dental attention that is available, and no time, money or thought has been spared to provide a place in which to carry on remedial and research work, which will be not only for the good of the children of Rochester, but for the good of children everywhere.

The dispensary was opened for work on October 15, 1917. The following is a statement of the work during the first year: Tooth treatments, 57,653; root treatments, 24,903; abscess treatments, 11; prophylactic treatments, 23; root fillings, 2,002; silver fillings, 20,168; cement fillings, 7,267; synthetic fillings, 2,776; gutta-percha fillings, 284; nitrate of silver, 654; capped, 198; crowns, 29; inlays, 3; extractions, 7,824; x-ray, 177; orthodontia, 784; number of visits to dispensary, 49,122; number of patients, 6,143; completed cases, 4,409.

The work was done by licensed dentists—recent graduates. While the work done consists principally of fillings and ordinary dental operations, it was done with the thought of preventive dentistry always in mind.

The work of cleaning the teeth of the children in the schools is done by squads of licensed dentists and dental hygienists, the latter being trained in the school for dental hygienists conducted by the dispensary. The squads are provided with a portable equipment consisting of a chair, engine, instruments, sterilizers, etc. All of the prophylactic work—the cleaning of the teeth—is done at the various schools and institutions, under careful and strict supervision.

It will be interesting to know that with the establishment of the school for dental hygienists a new vocation was opened for young women. The

term of instruction is one year. The salaries paid graduates are much larger than those usually received by young women, ranging from \$15 to \$40 per week. It is a field into which could be turned young women who have taken the places of men in war work, but which will be filled by men later on. The purpose of this school is not to educate women to become dental assistants except for the doing of prophylactic work, which the dentist in a full or busy practice finds more or less of a burden. These young women may be used to good advantage as dental assistants for the purpose of doing this work in the public school clinics and in manufacturing and business establishments where welfare work is carried on. They may also be employed to give talks and lectures on oral hygiene and other health subjects.

The dental operators and hygienists from the dispensary made the rounds of the schools in Rochester twice last year. They visited 40 public schools, 27 parochial schools and 8 orphan asylums. The first time the teeth of 33,664 children were cleaned and the second 41,860. After the teeth have been cleaned a survey is made of the mouth, and if other dental work is necessary, or pathological conditions observed, a card is sent to the parents of the child, calling attention to the necessity of at once correcting the trouble. Literature on the value of clean teeth and a clean mouth, printed in English, Italian, Yiddish and Polish is sent to the parents.

The work of the young women who have been doing prophylactic work has been most satisfactory, not only in Rochester but in many private dental offices. The Government has also placed its stamp of approval upon their work by giving employment to a considerable number to aid and supplement the work of the regular army dentist in hospitals in Washington.

A school lecturer is employed by the dispensary, who delivers illustrated lantern-slide lectures on oral hygiene and other health subjects. Lectures were delivered to 72,000 children last year.

From this recital of the activities of the Rochester Dental Dispensary, it will be observed that a considerable educational propaganda is being conducted. This will be necessary in any community on account of the woeful ignorance of the public of the value of dentistry in the conservation of health. From the very beginning of the work, it has met with the most cordial reception and approval. The school and health authorities are most enthusiastic and have rendered every assistance in launching this enterprise. While dental clinics are in operation in various places, nowhere else is there an attempt being made to clean the

teeth of all the children of a municipality twice a year or where any follow-up method has been inaugurated. There has been a noticeable improvement as regards attendance, and many cases could be cited of a considerable reduction in the number of repeaters, because of the correction of dental troubles. There has also been observed a wonderful improvement in discipline. It is easy to be seen that a child who has been awake all or part of the previous night, suffering from tooth-ache, as a result of bad teeth and bad mouth conditions, is not likely to have a sweet disposition in school the next day, nor can that child do its work in a satisfactory manner. Principals and teachers have stated that if this work had accomplished no other result than that of improving the dispositions of the children, it would be well worth the price.

During the influenza epidemic, the mortality among the children of Rochester was much less than that in other cities, and medical and dental men are of the opinion that it is largely due to the health talks and prophylactic treatment which the children received in the schools. The sanitary officer at Camp Wadsworth issued an order requiring that every man in the camp, including the officers, be required to line up in the streets of the camp five times a day and brush their teeth, and the mortality in that camp was less than in any other camp in this country. While credit for this may not be entirely due to the brushing of the teeth, it is the opinion of the medical men in charge of that camp that it was responsible to a considerable extent for the superior health conditions at Spartansburg.

The general hygienic conditions of the school children of Rochester have noticeably improved, and tooth brushes have become fashionable in families where there had been none, or where one was used by the whole family. In many cases the education of the child to appreciate the comfort and benefit of a clean mouth has resulted in an improved condition in other directions.

In starting a movement for the cleaning of the teeth of the children in any community, two matters must be decided: (1) Is it the intention to establish a clinic for performing the various dental operations? (2) Is it the intention to do only the prophylactic work—the cleaning of the teeth of the children?

If a clinic for the general practice of dentistry is established there will at once arise a wide divergence of opinion, and there will probably be much discussion about the advisability of establishing a central dental clinic or having scattered units throughout the city. From my own experience and that of others who have had to do with

the practical management of dental clinics, there is no question but that the central dental clinic is the proper one for a city the size of Rochester. It could be centrally located and easy of access by car lines. The matter of the supervision of the clinic is by far the most important consideration, if the best results are to be obtained. Recent medical or dental graduates are not very different from recent graduates of other schools or colleges. They are for the most part inexperienced and have had little practical clinical experience. They are not yet settled in proper methods of practice and their judgment is not mature enough to leave them to their own devices. Young people, with rare exceptions, are not inclined to be punctual in attendance and little realize the importance and the far-reaching benefits of proper and good service in medical and dental clinics. They should be under the strictest supervision, and this can be given only in a central dental clinic. The scattered units throughout a municipality would make the work of the chief administrative officer a most difficult one, because he would not be able to find sufficient time properly to supervise the work. It would, of course, be an ideal arrangement if a man of means or a municipality could be found liberal enough to provide sufficient funds to establish individual units and pay for the services of a proper supervisor for each, but this, I am

Operating unit, Rochester Dental Dispensary.

sure, would be found impossible in cities the size of Rochester. In the two cities—Boston and Rochester—which have central dental clinics, at various times there has been much discussion between medical and dental men with reference to central dental clinics or scattered units. Those who have advocated the central dental clinic idea, and who have had elastic and reasonable minds,

have been readily convinced, after an investigation and an observation of the work in a central dental clinic, that it is the most reasonable and sensible arrangement for cities of moderate size.

When there is a proper organization under central control, the argument in favor of a central clinic does not apply to the doing of prophylactic work in the schools, for the reason that only one kind of work is done. The work of the squads can be easily checked up to see whether it has been properly done. They are also under the supervision to some extent, and the observation all the time, of the principals and teachers, and can be required to account for their working time the same as other school employees. The expense and loss of time in bringing children to a central clinic for prophylactic work only, would be considerable and probably prohibitive in many communities. The arrangement which has been carried on in the schools of Rochester during the last year, has proved to be very satisfactory. Accurate account is kept of all receipts and disbursements for the school work, and surveys of the mouths of the children, with records of prophylactic work, are kept in each school building. When a child is transferred from one school to another the records go with him. This is done for the purpose of being able to make a comparison of the benefits of the dental work of whatever period may be decided upon.

The municipal authorities, and the people of Rochester generally, strongly support this work. No obstacles have been placed in our path by the municipal authorities, and we have not been hampered by interference or requests for the appointment of individuals to the various positions. The board of education, the health department, physicians and dentists have cooperated to the very fullest extent, and much of the credit for this work is due to their sympathy and support. The records of the work done are open to the public at any time, and it is always a pleasure to give all the information possible to those who come from other cities. It will be our greatest pleasure to assist in forwarding this work in other communities.

The education of the public to an appreciation of the tremendous advantages that come from a clean mouth and good teeth, should be one of the important functions of organizations. Any movement that has for its object the improvement of the physical condition of man, naturally increases the efficiency of the individual and tends to prolong life. There is absolutely no question but that proper attention to the mouth and teeth will do these things.

It is surprising to learn that not more than 10

per cent of the inhabitants of this country regularly employ a dentist, or appreciate the value of dental service. In the development of a health campaign due consideration should be given to the available number of physicians and dentists. There are not to-day dentists enough properly to look after the teeth of a sixth of the population of this country. In educating people to appreciate this service, it will also be necessary to increase professional educational facilities, and make the work attractive enough to induce young people to take up professional work.

MEDICAL SERVICE UNDER COMPENSATION ACTS

Dr. Royal Meeker, United States Commissioner of Labor, in an address on the subject "Lacks in Workmen's Compensation," at the annual meeting of the American Association for Labor Legislation at Richmond, Va., December 28, 1918, said:

"The provision for adequate medical, surgical, and hospital treatment for injured workers is far more important than the allowance of money benefits. Yet four states make no provision whatever for such services. Twelve limit the cost to \$100 or less and sixteen limit the period to thirty days or less. Pennsylvania, which probably contributes more fatalities and seriously disabled injuries than any other state, generously allows a maximum of two weeks' medical attention if it doesn't cost more than \$25. Only four states permit of adequate medical and surgical treatment by placing no limits in their laws upon the time or cost of such services. Massachusetts, perhaps deserves to be included with the four states because, although the law limits such services to two weeks, except in special cases, the Massachusetts Industrial Accident Board makes a special case of every serious injury. Washington has no limitation either as to time or amount, but requires the injured workman to pay one-half the cost, which operates as a decided check on proper treatment. The fact that the law puts no limitation on medical services does not mean that all workmen receive all needed medical and surgical treatment of the very best quality.

We should surely devote a large proportion of our time, energy, and intelligence to teaching the great truth that it is better and cheaper to pay competent doctors and surgeons to save lives, limbs, and bodily functions than to pay compensation therefor. The plant manager, the company doctor, the insurance companies, and the public are still living in the early Middle Ages, so far as the correct view of the medical question is concerned. Alas, few of the compensation commissions are much more enlightened. The workman who suffers injury must be restored physically, mentally, and morally as quickly and as completely as possible. When he has been as completely rehabilitated as possible, he should be put back into industry. This may and generally will involve his retraining either for his old job or a new job better adapted to his particular disability. The industrial accident boards and commissions must have a voice in this work of restoration, retraining, and reemployment of injured workers. The Smith-Bankhead bill now before Congress provides for Federal aid on a fifty-fifty basis to the States which will undertake the rehabilitation and reemployment of industrial cripples.

THE MONTH IN MEDICINE

Survey of Current Medical Literature with Editorial Comment

WALTER W. HAMBURGER, M. D., Editor

STAPHYLOCOCCUS AUREUS PNEUMONIA

Our conceptions of respiratory disease have undergone very widespread change, largely as a result of experience in these conditions during the war. Particularly our conception of the pneumonias has been very materially broadened to include the great variety of inflammatory conditions of the lungs due to a variety of different agents. This family of the pneumonias has recently received an addition through the contribution of Chickering and Park¹ under the caption *Staphylococcus aureus* pneumonia. They report from Camp Jackson (Columbia, S. C.) a series of 153 cases from among 8,100 influenza patients admitted to the medical service in which the clinical picture was entirely different from the usual influenza pneumonias.

"These patients were extremely prostrated almost from the onset of their infection. After being ill from three to four days with influenza, their condition became critical. They exhibited an unusual type of cyanosis. The cherry-red, indigo-blue color was indeed very striking, though not pathognomonic of the infection to be described more fully, that associated with *Staphylococcus aureus*."

The most striking clinical features are described as a picture of a general septicemia, with a high temperature, 104° to 106°, a relatively slow pulse, and with an atypical pneumonitis. The disease usually pursues a rapid course, from one to ten days. The sputum is quite characteristic, being of a "friable, purulent material of a dirty salmon-pink color resembling anchovy sauce or the contents of an over-ripe furuncle." Gram stains of such sputa show field after field of Gram-positive group cocci and pus cells, which appearance is said to be of grave or fatal prognostic import.

Staphylococcus aureus has been found in the blood stream at the Hospital of the Rockefeller

Institute in 53 per cent of the cases. It may also be found in the pleural fluid.

X-ray examination of the lungs in these staphylococcal pneumonias shows a diffuse mottling of the entire chest, rarely a typical lobar consolidation.

Pathologically, one finds in the lungs multiple minute abscesses and petechiae just beneath the pleura, while the cut surface of the lung may be intensely hemorrhagic or have the appearance of a confluent bronchopneumonia. The abscesses may be distributed throughout the entire lung and of variable size with *Staphylococcus aureus* being recovered in pure culture from them.

Treatment, as in the other pneumonias of the army camps, has been extremely disappointing, such things as digitalis, camphor in oil, infusions of sodium chlorid, glucose and various other measures being ineffectual.

The outlook, therefore, is extremely bad, and this organism is found in a very high percentage of the fatal cases.

Comment.—While Chickering and Park consider the cherry-red, indigo-blue cyanosis, fulminating course, the lack of definite signs of consolidation of the lungs, the dirty salmon-pink purulent sputum and the leukopenia striking features of this disease, it should be said that these features are found in many of the other severe respiratory infections due to other organisms. For example, a practically identical clinical picture was noted in the severe measles pneumonias associated with hemolytic streptococcus and also in the fulminant influenzal bronchopneumonias in which a variety of organisms, with or without the staphylococcus, was present.

While one would not wish to take issue with Chickering and Park, one feels that the cyanosis, the hemorrhagic sputum, the leukopenia, and the severity of the disease are probably to be considered as evidence of a severe overwhelming toxemias (possibly sepsis), which may be due to any one or more of a group of highly virulent organisms.

¹ Chickering, H. T., M.D., and Park, James J., Jr., M.D., Camp Jackson, Columbia, S. C., Jour. Am. Med. Assn., 1919, Ixxii, No. 9.

Nevertheless, the authors have called attention to what may prove to be a new clinical entity among the pneumonias, and of which one desires to hear more details. The recognition of this type of pneumonitis, as in most of the recent contributions from the army camps, necessitates the close cooperation of clinician and laboratory worker.

ANTITUBERCULOSIS MEASURES

Anyone who can shed new light on an old subject and present it from a fresh viewpoint is entitled to much consideration. Krause² has done this in the March number of the *Bulletin of the Johns Hopkins Hospital*. Although tuberculosis, like the poor, will probably always be with us, his address, "Some Aspects of the Problem," breathes such a spirit of optimism and confidence that all interested in pulmonary tuberculosis, professionally or personally, will derive new courage and inspiration.

Krause emphasizes the fact that the behavior of the human being is of more importance than the activity of the tubercle bacillus itself; that efforts should be directed to the supplementary reeducation of physician and laymen alike; and that "tuberculosis may have its birth in any and every event that makes man unhealthy."

"I would have them told that to be spat upon or coughed upon by the man with the 'common cold' did not upset me because I might merely acquire a cold, quite so much as that this cold might fan my quiescent pulmonary tubercle into phthisis. I would have them told that the delicate woman who was about to fulfill her grandest function should be handled just a little differently from the sturdy one,—that her labor should be shortened, that her lactation be directed with the possibility of manifest tuberculosis ever kept in mind. I would have them told that over-strain, whether physical or mental, or that dissipation was to be avoided, not because it lay them open to infection, but because it supplied the oil to a wick that was already present."

Krause emphasizes anew the universality of tuberculous infection from early infancy or childhood, as revealed by the Pirquet test, and that although we all have it, few of us are sick; that "before adolescence tubercle is more common than hair on the face, and after forty, more common than hair on the head; and in a great proportion of instances not so troublesome," unless the patient makes it so.

His reference to tuberculosis statistics showing that "tuberculosis mortality rate began to decline in practically every country that was advancing

industrially and was therefore increasing in wealth, as early as 1850"; that tuberculosis therefore declined before Koch's discovery of the bacillus, and before any modern scientific means of combating the disease had been instituted," is of striking interest and deserving of wide recognition and comment.

Such facts are surely of great encouragement, and, as Krause points out, are undoubtedly related to the "gradual bettering of the conditions of labor and living of the mass of the people."

A third item of interest, and really the only pessimistic note in his discussion, is his analysis of the spread of tuberculosis in early undetected cases. He points out the danger of the man, woman or child with a positive sputum, working and living in communal relations with his fellows, not knowing that he is ill, not consulting a physician for months or perhaps years, and the probable widespread dissemination of disease during this period. He comments on the difficulties in making an early positive diagnosis in the hands of skilled men even when a physician is consulted, and of even greater difficulty in the hands of the unskilled. He speaks of a prominent pediatrician who "presents himself to the pthysiologist for the first time twelve years after his cough had begun, and arrives with both lungs 'riddled' and sputum loaded with bacilli; of an eminent judge who first asked for advice thirty-five years after his disease had given out its first warnings, who came with cavitation in both lungs and a sputum count that would have caused Gaffky to create a new classification; of the pathologist who for eight years had the symptoms that we classify under the cardio-gastric type of onset and who finally went on to bilateral disease; yet although under constant observation by the best men, he was not declared tuberculous until bacilli appeared in his sputum after nine years."

Comment.—The therapeutic lesson from all this is clear. All of us should keep constantly in mind and should insist on the avoidance of mental and physical strain, over-fatigue, worry, unsanitary living, insufficient diet in those predisposed or frail individuals in whom the likelihood of a flaring up of their healed or latent tuberculosis is present. The war, with its deprivations of all bodily comforts, with its protracted worry and anxiety, with its superhuman effort and speeding up of all human endeavor and activity, undoubtedly ignited many latent fires. Now that it is over, and the period of reconstruction is here, physical and mental reconstruction should be and will be given extended thought and consideration. With the betterment of industrial and labor conditions, with the higher wage for the laboring

² Allen K. Krause, *Bulletin of the Johns Hopkins Hospital*, 1919, xxx, No. 337, p. 337.

classes, with better food, shorter hours, more leisure, all this will tend to lower the percentage of developed cases of tuberculosis. Constant instruction and education of the community regarding the advisability of patients presenting themselves to their physician early and continuously when a persistent cough, loss in weight, afternoon temperature, a general feeling of run-down and malaise will help to detect the early cases and diminish the danger of spread.

TACHYCARDIA AND MITRAL DISEASE

Treitschke held that war is the saving grace and redeemer of nations. While most of us may disagree, one cannot but feel that the present war has, if nothing else, done two things for this country.

First, it has acted as an energizer of many branches of activity; social, communal, industrial, scientific (medical).

Second, it has ruthlessly revealed our national deficiencies, silhouetting them against the heavens so that all may see. Furthermore, in most instances the war has probably done both of these things simultaneously.

In this connection the science of cardiology has likewise been given new impetus.

In the study of the tachycardias much excellent literature has appeared. For example, Benjamin and Brooks,³ in their examination of soldiers, describe a test which they feel has been of much aid in the differential diagnosis of the tachycardias; these they divide into the simple and persistent. The simple, or nervous tachycardias (neurotachycardia) occur in patients with irregularities in breathing, who are "fidgety," have coarse, irregular tremors, often confined to one hand or the other, stopping during conversation, in whom there is frequently some hesitancy in speech. The individual is simply excited. In nearly all such cases, placing the patient in the dorsal posture causes an early or delayed diminution of the pulse rate.

The persistent tachycardias are described as occurring in patients who are usually not excited, in whom there is a poor response to exercise, with a somewhat anxious look, with inordinate sweating, with a history of poor sustaining powers in games dating from some infection, such as rheumatism, grip, pertussis or measles; with various types of sensations in the region of the precordium at irregular times (described as a burning, actual pain, or a feeling of fullness or heaviness); with palpitation or a consciousness of rapid heart rate (especially in recumbent posture); with spots appearing before the eyes, and giddiness but seldom actual fainting; headache,

As a means of analysis of these cases of rapid heart, Benjamin and Brooks³ describe the following procedure as being of aid in differentiating this neurotachycardia from the persistent tachycardia (neurocirculatory asthenia). "The individual, on direction, drops the head and bends forward to about an angle of 45 degrees, whereupon the rapid heart will retard to a remarkable degree very quickly, sometimes to half of the original rate, if the case is one of simple tachycardia. The other type is not affected at all. The rate in a bending position corresponds fairly accurately to the rate in a recumbent posture. The test has been applied in a very large number of cases so far with very gratifying results. A certain number of soldiers who have responded to this test have been followed up. They are doing full duty. This adjunct, in the disposition of a rather difficult group of cases, is recommended for further use and comment by members of the service and the profession.

Mitral disease has likewise been the recipient of much new observation and study. Morison⁴ discusses the value of amyl nitrite inhalations in the diagnosis of mitral stenosis. The effect of amyl nitrite on the heart is very similar to the effect of exercise in promoting a more rapid cardiac circulation, particularly in hurrying the passage of blood through the auriculoventricular orifice, thereby intensifying a presystolic murmur, bringing out a suspicious latent one, or causing a slight unclarity, not due to mitral disease, to disappear. The use of this test is said to have advantages over that of exercise, in that it eliminates the attending dyspnea of the latter. "In other words, as the patient administers the drug to himself the observer listens at the apex of the heart until the desired effect of the drug is produced. In this way several phases of increasing cardiac activity are observed." Morison's original observation has been confirmed by several different observers.

Rothschild⁵ discusses several additional interesting points in mitral stenosis and concludes that from his observation mitral stenosis is not an uncommon valvular disease in men between 21 and 31; that only 40 per cent of his cases gave a definite history of acute articular rheumatism; that early cases required careful examination, as the murmur is variable; that the presence or absence of a thrill is of little value; that it must be differentiated from the over-acting heart (the

³Benjamin, Julien E., M.D., and Brooks, Ernest R., M.D., Camp Funston, Fort Riley, Kan.: "Two New Diagnostic Methods for Patients with Cardiac Disease." *The Journal of the Am. Med. Assn.*, lxxii, No. 9, 707.

⁴Morison, R. A., *Brit. Med. Jour.*, April 20, 1918.

⁵Rothschild, Marcus A., M.D., Camp Devens, Ayer, Mass.: "The Diagnosis of Mitral Stenosis." *The Journal of the Am. Med. Assn.*, lxxii, No. 9, p. 652.

neurocirculatory asthenia complex); that the ocular-pupillary pressure has proved of great value in differentiating the two conditions, particularly in rapid hearts; that Morison's amyl nitrite test is of special value in cases of slow acting hearts.

By these two means, therefore, we have at our disposal measures of easily and safely slowing or speeding up the heart rate, so that obscure, early mitral diseases may be detected or ruled out.

Peabody and Wearn and Tompkins,⁶ from studying the basal metabolism in cases of the irritable heart of soldiers as well as from studies regarding the effect of the injection of epinephrin, conclude that hyperthyroidism does not play a significant role in the production of the symptom complex of the irritable heart of soldiers, but that a certain percentage of them reacting to epinephrin show that the tachycardia is an expression of an over-activity of the sympathetic nervous system.

HEMOLYTIC STREPTOCOCCI IN THE FAUCIAL TONSIL

Pilot and Davis⁷ have just completed an interesting piece of work on the subject of streptococcus carriers. They made swab cultures of the pharynx and tonsillar surfaces of 100 patients and from the crypts of excised tonsils of the same individuals immediately after extirpation with particular reference to the frequency and predominance of hemolytic streptococci.

Most of these patients were children between the ages of five and sixteen years who showed hyperplastic but not markedly diseased tonsils.

Sixty-one per cent of the swab cultures and 97 per cent of the erypts of these excised tonsils showed hemolytic streptococci, indicating the enormous high percentage of these organisms in the throats of individuals without fever, subjective symptoms of sore throat, or recent acute inflammation.

This group was further compared with a study of the throats of normal persons whose tonsils had been totally or partially removed some time previous, this comparison being made with the view to determine the possible influence of tonsillectomy on the occurrence of hemolytic streptococci in the throat. The results of this study showed hemolytic streptococci in only 25 per cent of the swab cultures and in 58 per cent from the tonsils; in other words, a marked reduction as compared with the throats of patients whose tonsils had not been removed.

⁶ Peabody, Major Francis W., M.C., U.S.A., Wearn, Lieut. Joseph T., M.C., U.S.A., Tompkins, Edna, U. S. Gen. Hosp. No. 9, Lakewood, N. J.; The Basal Metabolism in Cases of the Irritable Heart of Soldiers, Med. Clinics of N. A., Sept., 1918, p. 507.

⁷ Pilot, L. and Davis, D. J.: Hemolytic Streptococci in the Faucial Tonsil and their Significance as Secondary Invaders, *Jour. Infect. Dis.*, 1919, xxiv, No. 4.

The most important conclusions which Pilot and Davis reached from their studies are the following:

"Hemolytic streptococci are common in the normal and diseased throat. The chief foci of these organisms are the crypts of the tonsils.

"Hemolytic streptococci were recovered by swab cultures in sparse numbers from the pharynx and tonsillar surfaces in 61 per cent of throats, chiefly children with hyperplastic tonsils; and from the crypts of the excised tonsils of the same individuals in 97 per cent, usually in predominating numbers. Swab cultures are therefore unreliable in determining the incidence of this organism in the respiratory tract.

"The frequency of hemolytic streptococci is decidedly less in the throats of persons whose tonsils have been extirpated than in the throats of persons with normal tonsils.

"These streptococci agree in the main in their morphology, cultural characteristics, fermentation reactions and pathogenicity for rabbits, and are practically identical with hemolytic streptococci isolated from various human pathologic sources.

"Hemolytic streptococci from the crypts of the tonsils are probably the most important source of the streptococcus complications of the various acute infectious diseases, and of the terminal infections."

Comment.—This contribution of Pilot and Davis is a noteworthy one in the study of streptococcus carriers. It has been shown by many observers, particularly in the respiratory complications of measles and influenza, that the hemolytic streptococcus is to be considered a secondary invader in these complications and the causal organism of many of the severe bronchopneumonias and empyemas occurring in the recent epidemics, in both military and civil communities.

The conclusion from this work obviously is, that inasmuch as the tonsillar crypts harbor hemolytic streptococci and the removal of tonsils reduces the percentage of carriers, therefore tonsillectomy would be expected to reduce the chances of severe secondary infections and complications.

That the removal of the tonsil is indicated in many chronic carriers in diphtheria and meningitis has been repeatedly demonstrated. With this new indictment of the tonsil, as a harborer of streptococci, new evidence is submitted as an argument for its removal as a prophylactic measure in the prevention of secondary pneumonitis and pleuritis.

Pilot and Davis emphasize the role of the tonsil as a streptococcus carrier from a new point

of view, and one which is worthy of wide recognition and consideration. It will now be interesting and probably valuable to consider the tonsils from this viewpoint in all acute infectious disease, and to ascertain clinically whether secondary streptococcal complications occur more frequently in patients with old hyperplastic tonsils than in those whose tonsils have been removed. Likewise, in the segregation of measles patients, and those with other acute respiratory infections, the streptococcus carriers and non-carriers (similar to the work of Levy and Alexander) one will, in the future, inspect the throats of these groups with this work in mind.

STUDIES IN LUNG ARCHITECTURE

Any one attempting to interpret the various markings in an x-ray plate of the chest has noted the countless number of shadows which escape explanation. One is usually contented in calling these "hillus shadow," "lung marks," or "tracery," normal lung structure without essaying a finer definition.

Beginners in radiography often interpret these normal markings as evidence of pathology, and only after considerable experience in checking up with the clinical history and physical findings are they willing to admit their error. Any work which will aid in the solution of this extremely difficult branch of x-ray diagnosis is of greatest value.

In this connection Miller⁸ has contributed, not only a very valuable piece of work, but has likewise developed a careful technic for further study.

By the use of a differential injection mass, consisting of a suspension of corn starch in 70 per cent alcohol, to which vermillion granules are added when it is desired to obtain a uniform dense shadow, and ultramarine blue granules when a less dense and finely granular shadow is desired, he has made studies in the injection of the bronchi, pulmonary arteries, and the pulmonary veins in an attempt more accurately to define normal lung architecture.

The summary of his findings is as follows:

The pulmonary artery follows in all of its subdivisions the subdivisions of the bronchial tree and may be recognized as comparatively dense, linear markings along the lateral wall of the bronchi.

The main pulmonary veins, on the other hand, can be made out on the medial side of the stem bronchus, but in its ultimate distribution, its branches are not associated with the bronchi.

In reading x-ray plates care should be exercised not to mistake these linear markings for density produced by pathologic changes.

Ring-like shadows with sharp borders that ap-

pear along the bronchi are often due to the plane that the bronchi bear to the observer.

Comment.—This study suggests once more the importance of the knowledge of lung structure in interpreting densities cast on the x-ray plate.

EXAMINATION OF THE HEART AND GREAT VESSELS BY MEANS OF THE X-RAY

Within recent years very much progress has been made in radiography of the gastro-intestinal tract. The heart and great vessels of the chest have received less attention. Holmes⁹ has contributed a timely article to this subject.

In his exceedingly practical discussion, he emphasizes the importance of an accurate technic and record system; the taking of plates at six feet in order to obtain parallel rays cast by the heart shadow; the frequent discrepancy between the outline of the heart as obtained by percussion and by the x-ray.

He includes the heart-sheet used at the Massachusetts General Hospital, as well as a table copied from Claytor and Merrill, giving the average normal measurements of the adult heart.

He discusses and illustrates accurately ptosis of the heart, aortic regurgitation, mitral disease, diffuse enlargement of the heart due to dilatation, and general enlargement of the heart, due to fluid in the pericardium and adhesive pericarditis, specific aortitis, and aneurysm.

THE DIAGNOSIS OF ACIDOSIS

Much has been written on acidosis, but apparently the need for more and continued instruction still exists. Macleod¹⁰ gives a fairly complete readable discussion of the present status of this illusive phenomenon. In particular he calls attention to Sellards'¹¹ simple test, viz., under normal conditions only five grams of sodium bicarbonate can be taken a day without making the urine alkaline. When the alkaline reserve, however, is seriously depleted, that is, when acidosis exists, large quantities of bicarbonate, even as much as 100 grams a day can be taken without making the urine alkaline. This test has been found of particular value in the diagnosis of acidosis accompanying certain forms of renal disease. He concludes that Sellards' method is no doubt the best test of acidosis at present available in routine clinical work.

⁸ Miller, Wm. Snow: Stereo-Roentgenograms of the Injected Lung as an Aid to the Study of Lung Architecture, Bull. Johns Hopkins Hosp., 1919, xxx, No. 336.

⁹ Holmes, George W., M.D.: The Medical Clinics of North America, Boston No., 1918, No. 4.

¹⁰ Macleod, J. J. R., M.D.: The Diagnosis of Acidosis, Jour. Laboratory and Clinical Medicine, 1919, iv, No. 6.

¹¹ Sellards: Principles of Acidosis, etc., Harvard University Press, 1917.

Comment.—This simple method of estimating the alkaline reserve can be used not only in routine ward work, but in private home practice as well and is a valuable aid, for example, in the dif-

ferential diagnosis of edema, in attempting to localize primary responsibility for the dropsy, either in heart or kidney, in the presence of an associated acidosis.

COLLECTIVE ABSTRACT

SOME PHASES OF THE RECENT INFLUENZA EPIDEMIC

BY JEROME E. COOK, M.D., ST. LOUIS, Mo.

IT has seemed advisable in preparing the present article to depart a little from the traditional scope of these collective abstracts by including not only a review of the more recent literature, but also some mention of the observations made in the course of previous epidemics. Several considerations have urged toward this course. In the first place the articles dealing with the present epidemic of 1918-19 contain for the most part few if any references to the literature, the several authors being content in the stress under which most of the work was done merely to set down the result of their observation without the usual appended references. Then again, the fact that it has been some thirty years since influenza was prevalent in the world has made the present pandemic seem quite like the appearance of a new disease. It is not surprising, therefore, that certain facts concerning epidemic influenza, as, for instance, its remarkable fatality in pregnant women, should be set down as if newly discovered, whereas the same observation can be found in the literature of almost every epidemic since 1556 when it is recorded that "abortions and death of child-bed women were common." When we have gone over the literature of these former outbreaks, we cannot but echo the words of Struem-pell, who, writing in 1890 of the epidemic that has just swept over Europe, says: "The description of the clinical picture in previous epidemics, particularly that of 1830, is so complete that aside from accurate description of the temperature course—consecutive regular readings not being practised then—there is little new to add."

But if we had been able to add nothing to our knowledge of the clinical features of the disease, how have we fared in our attempts to gain a better knowledge of its pathology and bacteriology? Technical methods in these branches have been greatly improved in the past thirty years, and we might reasonably expect some real addition to our previous knowledge. Nor shall we be disappointed in this though we are yet far short of a decision concerning the microorganism or microorganisms

responsible for the disease and the exact relation to each other and to the disease itself of the several pathological conditions found in the lungs:

As to the various types of lung lesion there seem to be two fairly divergent views: The one which would divide the lung condition into rather distinct types and speak separately of the bronchitis, the lobar pneumonia, the bronchopneumonia and the interstitial pneumonia; the other, more prevalent view which groups these various lesions as part of a single process, the pathological picture in any given case depending not upon a difference in kind, but simply in the degree of involvement and the time it has existed. Thus the British Medical Research Committee gives the following picture of a typical autopsy:

There are 200 cc. of blood-stained watery fluid in the left pleura. The parietal pleura on both side is injected and contains scattered purpuric patches. The pericardium contains a little blood-tinged fluid. The lower lobe of the left lung is dark purple; there is a fine fibrinous roughening in places; it is heavy and retains its shape; to the feel it is soft and jelly-like with firmer areas scattered about. The upper lobe is similar in the posterior part but anteriorly is spongy and aerated. On section the lower lobe is of a dark red colour and airless, being full of a thin hemorrhagic exudate which flows out from the cut surface. In the firmer areas are found solid, dark red, rather dry areas. Some of these extend to the surface and resemble infarcts, others are rather spherical and located centrally. The bronchial tree is intensely injected and contains bloody fluid which pours out into the trachea. The cervical and paratracheal glands are injected, the latter a dark purple. The hilus glands are enlarged, very soft and hemorrhagic. The spleen is not enlarged. The patient appears to have been drowned by the lung exudate rather than killed by the toxemia. In cases of longer standing there is in addition a marked bronchopneumonia with pus in the smaller tubes and sometimes areas of grey hepatization. In several cases a purulent bronchitis and peribronchitis exists, the lung presenting a marbled appearance owing to the purulent infiltration of the bronchial wall.

To this description might be added that there is often, probably in more than one-fourth of the cases, localized abscess-formation within several or many of the patches of pneumonic consolidation. These abscesses are a somewhat later phenomenon and are superimposed upon the pneumonic process. True empyemas may likewise occur late, but are not frequent. In about 10 per cent of the cases with severe lung involvement

there is an interstitial emphysema brought about by rupture of distended air sacs in the lung, dissection of the air back along the blood vessels to the hilum, then through posterior and superior mediastinum to the tissues of the neck.

Many observers make rather sharp distinction between the lobar pneumonic and the bronchopneumonic type of the lung lesions. It is difficult to see a clear justification for any such division. In certain very severe cases dying early there is a state of engorgement of the lungs which can best be described as lobar. There are many facts in favor of the contention that the so-called "lobar" form of the latter stages is only a phase of the bronchopneumonic form brought about by a fusion of many bronchopneumonic areas. Even those who make claim for the lobar pneumonic form do not describe the typical picture of lobar pneumonia, the granular cut surface, the fibrin plugs, and the fibrinous pleurisy with "shaggy" exudate; and certainly the clinical course, aside from the frequent onset with chill, is not of the lobar type. One misses the characteristic fever curve, the leukocytosis, and the rusty sputum. So that it may be best to adhere to the view of Ribbert that, although the pneumonia may be lobar in distribution, it is not so in type.

Naturally enough, the greatest interest in the present epidemic has centered on the question of etiology, not alone as a scientific problem of its own, but as a guide to more effective methods of prophylaxis and treatment. What is the causative agent of influenza? What is the causative agent of influenza pneumonia? What role do the various bacteria found in the lungs play in the course of the pneumonia and what relation do they bear to the mortality? May the pneumonia be caused by any one of several different organisms? At the close of the epidemic of 1889-90 the opinion prevailed that the disease, or at least the pneumonia, was probably caused by the streptococcus which was found so frequently in the sputum and in the lungs at autopsy. Nevertheless there existed a very healthy skepticism about the matter, and when Pfeiffer a few years later ascribed to the influenza bacillus the entire blame for the disease his view seemed to meet with almost universal acclaim and has prevailed, though not without challenge, until recently. The case against the bacillus of Pfeiffer may be stated briefly thus: Most investigators are unable to find the influenza bacillus in anything like 100 per cent of influenza cases; when found, it is rarely in pure culture; it is found in a large per cent of patients suffering with measles, pertussis, and other diseases with respiratory manifestations and might with equal reason be urged as

the cause of any one or all of these diseases; it is likewise a frequent resident of the normal pharynx; it has not been shown to fulfill the third of Koch's postulates; when found in the lungs of patients dying of influenza pneumonia, it is almost invariably associated with other organisms of known pathogenicity and it is quite unreasonable to suppose that these other organisms, among which are the pneumococci, the *Staphylococcus pyogenes*, the bacillus of Friedlander, and the *Streptococcus hemolyticus*, are secondary invaders and not primary factors in the pneumonia, even if it be granted that the *Bacillus influenzae* may be responsible for the disease in its uncomplicated form. None of these arguments have gone unchallenged. An increasing number of bacteriologists testify to the almost constant presence of the Pfeiffer bacillus in the upper air passages of influenza patients provided a properly refined technic be used for its demonstration. The bacillus is likewise present in a very large per cent of pneumonic lungs at autopsy and, considering the very low viability of the influenza bacillus, it has been suggested that it would be found in practically 100 per cent of autopsies performed promptly after death. It is at all events the most common organism found in these lungs; why should not the other organisms be looked upon as secondary invaders? Anatomically, the pneumonia is of a type entirely its own and bears little resemblance to any other pneumonic process except that caused by *Bacillus pestis*, as has been pointed out by Symmers. If the *Streptococcus hemolyticus* is responsible for the mortality in the pneumonia of influenza, it does not give rise to the anatomical picture of streptococcus pneumonia. A large opportunity for the study of streptococcus pneumonia existed during the previous year at the army camps; many of the same observers testify to the essential anatomical difference of the influenza and the streptococcus pneumonia. As to the inability to reproduce influenza in animals with cultures of influenza bacillus there is little to be said. The bacillus is not pathogenic for our usual experimental animals, and "it is well known that the monkeys in our zoos do not suffer during the epidemics." (Leichtenstern and Stocker). There are a few investigators who claim to have reproduced the disease in monkeys and man by the injection of bronchial secretions both before and after passage through a Chamberland filter, but their results are inconclusive, have not been confirmed and, in fact, are not in accord with similar investigations by others. All in all, the research along this promising line has been strikingly meager unless much of it remains unpublished. Attempts to demon-

strate a complement-binding factor in the blood of patients with influenza pneumonia using preparation of *Bacillus influenzae* as antigen have likewise been inconclusive. If any complement binding factor exists it must be quite weak. Yet there may be antibodies of another order as demonstrated by Parker, who obtained a highly toxic substance in the filtrate of cultures of influenza bacilli. Two cc. of this toxin killed a medium size rabbit in three hours. Repeated small immunizing doses protected rabbits against a lethal dose. The serum of rabbits so protected will protect other rabbits either by mixture with the toxin *in vitro* or by injection just before or after injection of the toxin.

Thus far, then, nothing has been settled. Those who would have the bacillus of Pfeiffer the prime agent in the causation of influenza and its complications have much evidence in their favor. Yet they have by no means proved their case. The possibility that the disease is due to a virus similar to those which are responsible for the acute exanthemata cannot be denied; it is thus far nothing but an attractive theory with several points in its favor.

The association of pregnancy and influenza has attracted considerable notice in the present epidemic on account of the startling fatality of the disease when it attacks pregnant women, particularly during the latter months of gestation. As has been remarked before, this is no new observation, yet it would seem that the mortality among pregnant women has not been as extreme in some epidemics as in others. Indeed, it seems well established that there is considerable variation in the general severity of the several epidemics and this may likewise account for the fact that pregnant women fare better in some epidemics. However that may be, few will deny that the influenza of the recent epidemic has run an extremely unfavorable course in pregnant women and while few writers have published such appalling figures as Bland, who seems to claim that about 50 per cent of pregnant women with influenza die, yet none view the situation in any but a serious light and in any given locality the death rate among pregnant women has been very considerably increased during the epidemic. The mortality of influenza pneumonia is at least 15 per cent greater in pregnant than in nonpregnant women. Whether pregnant women are more susceptible to the infection in the first place is undecided. The frequent occurrence of abortion during the influenza does not affect either favorably or unfavorably the woman's chance of surviving and the induction of premature labor is rather generally decried as worse than useless. Norris

induced labor in three pregnant women who did not have pneumonic complication; they all recovered. It would seem, in view of the marked liability to, and fatality of the pneumonic complication, that interruption of pregnancy in the first hours of the disease might lessen the total mortality in pregnant women. No one except Norris appears to have been bold enough to carry out any such plan, and unfortunately his cases are too few to allow of any decision. As far as they go they are encouraging.

As to the therapy of the disease we must once more acknowledge our woeful ignorance. Nothing brings this home to us as clearly as the almost uniform death rate wherever the statistics are published. Most cases do well on general measures,—rest in bed, fresh air, etc. Camphor in large doses has been much praised by some. It was used in the epidemic of 1889 as well as in the present one, but does not seem to have met with any general acclaim. In fact, the only drug which has survived through the years with any measure of credit is opium.

Its ability to relieve in a measure the distressing pains, to improve the sleep, and to ameliorate the harassing cough is probably responsible for any good it may do, for in thereby lessening the strain upon that intangible factor, the patient's vitality, it conserves the only weapon of real resistance to the disease of which we have any knowledge.

A word remains to be said concerning serum therapy. A few papers have appeared dealing with the results obtained in treating influenza pneumonia with the whole blood or the serum of patients convalescent from the same disease. The results have been distinctly encouraging, but in a disease which differs so greatly in severity from time to time great caution is necessary in interpreting the results of therapy. Yet it is difficult to read the recent report of McGuire and Redden, who used the pooled serum of patients recently recovered from pneumonia in the treatment of early pneumonic cases, without feeling that it marks a distinct therapeutic advance. The serum must be used in fairly large amounts, 120 cc. being the average dose, and the problem of a sufficient number of suitable donors will be a distinct drawback to its employment outside of large hospitals. Nevertheless, if subsequent reports of the method confirm the results in these first one hundred cases a step forward will have been made in the struggle with a disease against whose ravages we have been comparatively powerless.

FAVOR CHANGED LICENSURE EXAMINATIONS

Dr. George Blumer, dean of the School of Medicine of Yale University, at a recent meeting of medical bodies in Chicago, spoke on the subject, "Desirability of Changing the Type of Licensure Examinations." A related topic was the subject of an address by Dr. John S. Rodman, secretary of the National Board of Medical Examiners, of Philadelphia, who read a paper on "Cooperation in Examinations by the National Board of Medical Examiners, the State Medical Licensing Boards and Medical Schools."

The question of medical licensure was a part of the program of the Annual Congress of Medical Education and Licensure and affiliated organizations, including the Council of the American Medical Association on Medical Education, the Federation of State Medical Boards, and the Association of American Medical Colleges.

Medical education, hospital standardization, annual registration of physicians, and related subjects were dealt with by speakers. Several medical officers of the army and navy were in attendance, including Brigadier General E. L. Munson, M.C.; Brigadier General F. A. Winter, Army Medical School; Lieutenant Colonel H. D. Arnold, M.C.; Rear Admiral E. R. Stitt, Navy Medical School; and Captain F. C. Waite, S.C.

Surgeon General Issues Request

The Surgeon General of the army desires that manuscripts on medical subjects written by medical officers retired from active duty and based on war experiences and official records be submitted as heretofore to the secretary, Board of Publications, Surgeon General's Office, Washington, D. C., as a courtesy to the Surgeon General. A carbon copy is requested. Upon approval the original will be forwarded to the journal designated for publication.

DISCUSS JEWISH HEALTH WORK

Jewish health work in the United States will be reviewed in perspective by the National Conference of Jewish Charities, which will take place May 27 to June 1, at Atlantic City, N. J. The morning and afternoon sessions on Friday, May 30, will be devoted to the discussion of health work. Dr. H. J. Moss, chairman, will present a report of Jewish health work. Discussion of the report will be led by A. Ray Katz, chairman of the Jewish Health Bureau, who assisted Dr. Moss in the recent health week conducted in Baltimore, Md., by the Jewish Educational Alliance. Health insurance, the influenza epidemic, hospital social service, convalescent care, and tuberculosis will be topics of discussion.

VICTORY MEETING OF A. M. A.

The Victory Meeting of the American Medical Association, as the annual conference has been named, is attracting such general interest in advance of the dates scheduled for the gathering, June 9 to 13, that the hotel capacity of Atlantic City, N. J., is being heavily taxed by early reservations. The local committee on arrangements will attend to reservations upon request. It has offices at 1801 Pacific Avenue, Atlantic City. Foreign governments are sending delegates, among them General Melis, Colonel A. Depage, Dr. P. Nolf, and Professor J. Duesberg, of Belgium; and Dr. Juan Guiteras, director of public health of Cuba; Dr. Emilio Martinez, of the National University of Cuba, and Dr. Julio Carrera, chief surgeon of the Havana Emergency Hospital, Havana, Cuba. For the convenience of members of the American Medical Association, the program of the National Conference of Social Work, which will meet in Atlantic City June 1 to June 9, has been so arranged that the health division and other divisions interested in health matters will hold their sessions toward the end of that week.

SOCIAL CONFERENCE MEETS IN JUNE

Those in charge of arrangements for the forty-sixth annual meeting of the National Conference of Social Work, June 1 to June 8, at Atlantic City, N. J., during the week preceding the Victory meeting of the American Medical Association, expect an attendance of more than 4,000 delegates. Dr. C.-E. A. Winslow, professor of public health at Yale University, is chairman of the health division, which has for its theme, "Health and the Standard of Living." Sir Arthur Newsholme, chief medical officer of the Local British Government Board, is coming from England, and Dr. René Sáñd, professor of social and industrial medicine at the University of Brussels, will attend from Belgium. Dr. C. Mulon, who had charge of the *creches* maintained during the war by the French government for the benefit of women workers in the munitions factories, represents France. The program of the health division is devoted to discussion of housing, family food supplies, tuberculosis, medical and nursing care, health insurance, infant mortality, industrial hazards, and venereal diseases. A health program for children will be considered by speakers in the children's division, while topics in other divisions include the problem of public aid for mothers, handicapped soldiers, and state care of mental diseases.

The monthly *Bulletin of the Department of Health of the City of New York*, for January, is devoted to a lengthy discussion of the drug evil and the drug law by Cornelius F. Collins, Justice of the Court of Special Sessions, New York City.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

DISPENSARIES—THEIR MANAGEMENT AND DEVELOPMENT.* A book for administrators, public health workers, and all interested in better medical service for the people. By Michael M. Davis, Jr., Ph.D., director of the Boston Dispensary, and Andrew B. Warner, M. D., superintendent of Lakeside Hospital, Cleveland, Ohio.

The title of this book is "Dispensaries" but the subject is largely medical service. While the history and extent of dispensaries and their equipment and organization are given attention, the book really deals with the dispensary "as a form of organization for rendering efficient medical service to the people." Its place is stated thus: "The dispensary represents an organized system for the practice of medicine in the treatment of patients who are able to go to see the doctor, just as the modern hospital represents the organized practice of medicine for patients who are sick enough to be in bed."

Section I of the book gives the historical view of the origin and rise of dispensaries. Section II deals with fundamental principles under the titles: "Who Are Dispensary Patients? Who Should Be Dispensary Patients? the Ten Essentials of a Clinic; Medical and Administrative Organization and Social Service."

Sections III and IV deal with technique and special types of dispensaries. Section V deals with public problems: "The Dispensaries and the Medical Profession; the Efficient Dispensary of the Future; Financing Better Medical Service; the Organization of Dispensary Service for a Community; and Conclusions." A bibliography is added.

Physicians will find this book of profound interest in these new times when medical practice is being adjusted to the new conditions of society. That there is bound to come a greater coöperative organization of medical service no observer can doubt. The lines of development indicated in this book are, therefore, worthy of the most careful study.

THE HUMAN MACHINE AND INDUSTRIAL EFFICIENCY.† By Frederic S. Lee, Ph.D., LL.D., Dalton professor of physiology in Columbia University; president of the American Physiological Society; consulting physiologist to the U. S. Public Health Service; chairman of the Subcommittee on Fatigue in Industrial Pursuits of the National Research Council, etc.

In this brief book Professor Lee has driven home some important industrial truths which should interest the physician as well as industrial managers and workers. In it he pleads for a physiological basis for employment and briefly points out the requirements for real efficiency.

The maintenance of working power from day to day and week to week is the object sought and to this end the author discusses the question of fatigue as it affects or is affected by the qualifications of the worker, resting periods, the length of the working day, night work, continuous employment and overtime work. The subject of women in industry is briefly discussed with the general conclusion "that the female body considered as a machine is different in certain respects from the male body and that the conditions under which the greatest degrees of efficiency can be secured for the two, respectively, are probably different in certain features."

Industrial medicine is discussed briefly with approval; food in its relation to efficiency is presented; scientific management is criticised because it concerns itself with improving material equipment while "in its dealings with the human machine it falls far short of the ideal;" vocational education is destined to be "only completely satisfactory when it is placed on a sound physiological basis."

Summarizing the subjects discussed, the author sets forth the outlines of a program in a paragraph as follows: "In our analysis of the conditions of efficiency we always come ultimately to the underlying fact that the worker is a physiological mechanism and must be treated as such. Here is the proper scientific basis for the organization of industrial work. We already have the promising beginnings of a science of industrial physiology. What is needed now is a great extension of the method of experiment, partly in laboratories, but especially in factories, by which facts may be accumulated, principles may be established, and this new science may be rationally developed. In this direction I believe that industry has in America today an unparalleled opportunity for progress."

THE HUMAN SKELETON.‡ An Interpretation. By Herbert Eugene Walter, associate professor of biology, Brown University, 214 pages, 175 illustrations.

The little volume cannot be considered as a serious scientific effort, but only as an interesting and well written story in which the bones of the body play the leading role. The beneficial results of popularizing science is doubtful. Such works are vague and superficial as far as science is concerned and therefore of necessity must attract the interest of the reader because of the rapidity of movement and a free use of the spectacular.

The author excuses the appearance of his book upon the grounds that in as much as each person possesses a skeleton of his own a better acquaintance with it should constitute a source of intellectual delight and satisfaction; and because the layman usually regards a consideration of his "insides" as an indelicate subject, and forbidding to one simply in quest of satisfaction of natural curiosity. The book is a popular equivalent of the excuses. H. W.

For Medical and Welfare Directors

FIRST AID IN EMERGENCIES

By ELDREDGE L. ELIASON, A.B., M.D. Former Lecturer on First Aid in Emergencies, University of Pennsylvania.
106 Illustrations. 215 Pages. \$1.50 Net.

The best and most compact book, with its convenient thumb index and illustrations, with which to meet all emergencies arising from accidents or sickness. It gives quickly understood directions for the treatment of all kinds of wounds, sprains, dislocations, fractures, burns, unconscious condition, poisoning, etc., etc., with special chapters on surgical principles and supplies, bandaging, hemorrhage and drugs.

HYGIENE OF THE EYE

By WILLIAM CAMPBELL POSEY, A.B., M.D. University of Pennsylvania.
120 Illustrations. 344 Pages. Octavo. \$4.00 Net.

None but an expert could give so effectively the essential points as to the structure of the eye, its care and protection in health and treatment in disease, with the intention of striking at the root of the large percentage of eye troubles and blindness in the American population. Dr. Posey bears a threefold relation to the subject: As practicing surgeon, as teacher in two great medical schools, and as Chairman of the Commission of Conservation of Vision in Pennsylvania. He has prepared a book of the greatest value to ophthalmologists, practitioners, and health officers, as well as for the individual. It is an authoritative and practical guide to the prevention and conservation of eyesight under all conditions and as such will prove of practical value to the members of the medical profession engaged in industrial work.

HOME AND COMMUNITY HYGIENE

By JEAN BROADHURST, Ph.D. Teachers' College, Columbia University.
428 Pages. 1 Colored Plate. 119 Illustrations. \$2.00 Net.

"This is nothing less than an encyclopedia of hygiene written in the simple style which makes it understandable and interesting to the most inexpert layman and yet so scholarly and authoritative as to command the respect of the scientific physician or sanitarian. For the professional library, for the school, for the family. It is to be commended in the heartiest and most unhesitating terms. It is of exceptional interest and practical value."—*New York Tribune*.

It is a practical textbook on the entire subject both from the individual and community point of view. Problems of sanitation and health are dealt with in helpful detail.

MOUTH HYGIENE

By JOHN SAYRE MARSHALL, M.D., Sc.D. Syracuse University.
2nd edition revised. 22 Illustrations. 12mo. \$2.00 Net.

The importance of mouth hygiene to public health is now receiving the attention it deserves. This little handbook covers the subject thoroughly. The facts given and the suggestions made are of the greatest value to those interested in community hygiene as well as to individuals. The author points out the connection between oral diseases and immorality, drunkenness, crime, and insanity. He discusses the prevalence of oral diseases, the care of the mouth under all conditions, and shows how special diseases of the throat, the ear, the eye, the stomach, intestines, etc., are caused by oral sepsis. There are also chapters on the psychological effects of dental and oral diseases and physical deformities, with a special chapter on the oral hygiene propaganda and the results of experimental work.

HIRSCHFELDER DISEASES OF THE HEART AND AORTA

By ARTHUR DOUGLAS HIRSCHFELDER. University of Minnesota.
Octavo. 732 Pages. 325 Illustrations. 20 Plates. Cloth, \$7.00.

"The present volume is the most complete work on the subject in the English language. Here pure science and practice are brought together, their inter-relations shown and what benefits we are to look for from scientific investigation. The book is a revelation in thoroughness. The very latest scientific appliances and method of their application, the value to be placed upon their findings are accurately represented. The clearness and brevity of the presentation, the liberality of the illustrations, the excellence of the arrangement, the experience of the writer should appeal to the medical profession."—*Maryland Medical Journal*.

FUCH'S OPHTHALMOLOGY

By ALEXANDER DUANE. Knapp Memorial Hospital, New York.
Octavo. 1067 Pages. 462 Illustrations. Cloth, \$7.00.

New 6th edition of this book of world-wide use and esteem is just ready. Frequently referred to the journal reviews as the ophthalmologist's bible—extended description unnecessary.

ELIASON'S PRACTICAL BANDAGING

Including Adhesives and Plaster-of-Paris Dressings

By ELDREDGE L. ELIASON, A.B., M.D. University of Pennsylvania.
Crown Octavo. 124 Pages. 155 Illustrations. Cloth \$1.50.

All the recognized classical bandages in common use are described, illustrated by bandages placed on living models, reinforced by drawings from photographs showing exactly the methods and turns, each turn numbered, in addition to which the author has added modifications found more efficient in his experience. The exact amount of material required is shown, how to roll, starting, requisites of a bandage and its ending—in a word, it is the most complete and practical work in existence describing the various bandages and dressings and their application.

SUBSCRIPTION

Domestic postage, \$3.00. Foreign postage, \$3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organize medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

BOOKS OF THE MONTH

(Continued From Page 92)

A MANUAL OF DISEASES OF THE NOSE, THROAT AND EAR.* By E. B. Gleason, M.D., professor of otology in the Medico-Chirurgical College Graduate School, University of Pennsylvania.

A new edition of the textbook which has long been a favorite amongst medical students. In this edition the author has thoroughly revised his text, omitting much of the antiquated and obsolete, and adding with brief but careful consideration recently demonstrated facts and theories. The reading matter is concise, the illustrations for the most part well chosen and numerous, the whole making an excellent book for the beginner in otolaryngology, and the general practitioner.

TUBERCULOSIS OF THE LYMPHATIC SYSTEM.† By Walter Bradford Metcalf, M.D., Associate in clinical medicine, University of Illinois, College of Medicine.

Metcalf has written a very readable monograph on a subject only too little emphasized, namely, glandular tuberculosis in childhood. His discussion is most complete, including a reference to the anatomy and physiology of the lymphatic system, etiology, pathology and symptomatology of the disease of tuberculosis of the lymphatic glands, diagnosis and treatment. There is a welcome, quite complete bibliography at the close. His references to the literature on these subjects is most complete and desirable. His enthusiastic championing of the tuberculin treatment and his dismissal of surgical treatment is in line with modern thought on this subject.

The book is attractively printed and illustrated. The chapters on treatment are particularly complete.

A TEXT-BOOK OF PHYSIOLOGY.‡ For medical students and physicians. By William H. Howell, Ph.D., M.D., professor of physiology, Johns Hopkins University. Seventh ed., revised. 8vo., 1,059 pp. 307 illustrations.

Howell's work must still be considered the leading American text-book of physiology. The seventh edition bears no fundamental change as to the arrangement of material, or the general principles of presentation. However, the work has been thoroughly revised and brought up to date as nearly as is possible. The text is lucid and the manner of presentation is direct and forceful.

But one criticism might be offered and that is the tendency of the author to compliment the mentality of the student by not drawing general conclusions in regard to disputed points and opposing theories. Such a tendency is highly valuable for the advanced student, but it tends to weaken the beginning student in his beliefs of the accuracy of the science and its fundamental value as an aid to a proper understanding of allied subjects of medicine. However, as the author explains, the best that a text-book can hope to accomplish is to give as clear a picture as possible of the tendencies of the times. This has been accomplished in an admirable manner.

Physiology is a rapidly growing subject which often requires readjustment of its theories. The thinking student should rapidly appreciate this condition and learn to evaluate data and draw conclusions from the facts or evidence presented. Dogmatic statements and submissive acceptance of such, especially where theories are concerned, can never advance science. Hence, the criticism offered above applies more to the reader than to the author.

Equal in Calories

The 30-cent package of Quaker Oats yields 6221 calories. It is equal on this basis to 80 bananas.

It Equals in Calories

50 Potatoes	22 Lbs. Perch
21 Cans Peas	9 Lbs. Veal
750 Oysters	89 Eggs

Meat and fish foods, on the average, cost over ten times Quaker Oats for the same energy value.

The oat is also a vastly better food. It is almost the ideal food in balance and completeness. It is whole-grain food.

There are many reasons, we suggest, why everyone should know this.

Quaker Oats

Flaked from Queen Grains Only

Quaker Oats is flaked from queen grains only—just the rich, plump, flavorful oats. We get but ten pounds from a bushel. It means an extra-flavorful oat dish without extra price.

BOOKS OF THE MONTH

(Continued From Page 22)

ABSTRACTS OF WAR SURGERY.* Prepared by the division of surgery, Surgeon General's office.

The Division of Surgery of the Surgeon General's office distributes to the medical personnel in each American military hospital a mimeographed copy of abstracts of selected surgical articles dealing with war surgical topics. These abstracts proved to be of such unqualified pedagogical value that it became necessary to publish them in book form. The abstracts are arranged topically and cover the subjects of wound treatment, tetanus, gas gangrene, abdominal injuries, cardiovascular surgery, joints, fractures, burns, anesthesia, trench foot, foreign bodies, jaws and face, and peripheral nerve injuries.

The volume furnishes an excellent resumé of the literature of war surgery from 1914 to 1919, and, although far from complete in its scope, nevertheless serves a marked utilitarian purpose.

A TEXT-BOOK OF GENERAL BACTERIOLOGY.† By Edwin O. Jordan, Ph.D., professor of bacteriology in the University of Chicago and in the Rush Medical College.

The sixth edition of this text-book of general bacteriology contains an entirely new chapter on the pneumococcus and an extensively revised one on the meningococcus, as well as new sections on infectious jaundice, rat-bite fever, and trench fever. A text-book which has gone through six editions in eleven years hardly needs further commentary on its excellence.

The only suggestion which one might wish to make to Dr. Jordan is that individual chapters on certain bacteria might be a bit more detailed and exhaustive. Although the book in its original preface modestly states it is only a general introduction to the subject, and that an exhaustive treatment has not been attempted, still with the increasing interest in infectious and bacterial diseases, and with the feeling that the physician should picture disease more and more in bacteriological and epidemiological terms, one feels a desire for more than seven pages of discussion of the influenza bacillus and ten pages of the meningococcus, or even fourteen pages of the pneumococcus. We wish Dr. Jordan would write not a text-book on general bacteriology but a system!

NEOPLASTIC DISEASES. A Text Book on Tumors. By James Ewing, M.D., Sc.D., professor of pathology at Cornell University Medical College, New York City. Cloth, pp. 1,027, illustrated, \$10.00. W. B. Saunders Co., Philadelphia, 1919.

THE OPERATIVE TREATMENT OF CHRONIC INTESTINAL STASIS. By Sir W. Arbuthnot Lane, Bart., C.B., consulting surgeon to Guy's Hospital and to the Hospital for Sick Children, Great Ormond Street. Fourth edition, revised and enlarged. Pp. 328, illustrated. Oxford University Press, Warwick Square, London, 1918.

ULTRA VIOLET RAYS IN MODERN DERMATOLOGY. Including the Evolution of Artificial Light Rays and Therapeutic Technique. By Ralph Bernstein, M.D., Philadelphia, Pa., professor of dermatology, Hahnemann Medical College, Philadelphia; clinical chief, Skin Section, Hahnemann Hospital Dispensary, Philadelphia; Pp. 162, illustrated. L. Achey & Gorrecht, Medical Publishers, Lancaster, Pa., 1918.

PRACTICAL PHYSIOLOGICAL CHEMISTRY. A Book Designed for Use in Courses in Practical Physiological Chemistry in Schools of Medicine and of Science. By Philip B. Hawk, M.S., Ph.D., professor of physiological chemistry and toxicology in the Jefferson Medical College of Philadelphia. Sixth edition, revised and enlarged. Illustrated, \$3.50. W. B. Saunders Co., Philadelphia, 1918.

SURGICAL TREATMENT. Volume III.—A Practical Treatise on the Therapy of Surgical Diseases for the Use of Practitioners and Students of Surgery. By James Peter Warbasse, M.D., formerly attending surgeon to the Methodist Episcopal Hospital, Brooklyn, N. Y. In three large octavo volumes and separate desk index volume. Pp. 861, 864 illustrations. \$30.00. W. B. Saunders Co., Philadelphia, Pa.

PERSONAL HYGIENE AND HOME NURSING. A Practical Text for Girls and Women for Home and School Use. By Louisa C. Lippitt, R.N., assistant professor of corrective exercises, University of Wisconsin; A head reconstruction aide in physiotherapy, Medical Department United States Army, etc. Pp. 256, illustrated. World Book Co., Yonkers-on-Hudson, New York, 1919.

WORLD-POWER AND EVOLUTION. By Ellsworth Huntington, Ph.D., research associate in geography, Yale University. Author of "Civilization and Climate," etc. May be briefly described as the influence of climate upon human affairs as applied to the momentous problems growing out of the World War. Cloth, pp. 287, illustrated, \$2.50. Yale University Press, New Haven, 1919.

THE HUMAN MACHINE AND INDUSTRIAL EFFICIENCY. By Frederic S. Lee, Ph.D., LL.D., Dalton professor of physiology in Columbia University; president of the American Physiological Society; consulting physiologist to the United States Public Health Service; chairman of the Subcommittee on Fatigue in Industrial Pursuits of the National Research Council, etc. Pp. 119, illustrated, \$1.10. Longmans, Green & Co., New York, 1918.

TEXT-BOOK OF CHEMISTRY. Inorganic and Organic, with Toxicology. For students of medicine, pharmacy, dentistry and biology. By R. A. Witthaus, A.M., M.D., late professor of chemistry, physics, and toxicology in Cornell University. Seventh revised edition by R. J. E. Scott, M.A., B.C.L., M.D., Fellow of the New York Academy of Medicine; editor of Witthaus' Essentials of Chemistry and Toxicology, etc., \$4.00. William Wood & Co., New York, 1919.

WAR SURGERY OF THE FACE. A Treatise on Plastic Restoration after Facial Injury. By John B. Roberts, A.M., M.D., F.A.C.S., professor of surgery in the University of Pennsylvania Graduate School of Medicine; lecturer in the Civilian School of Plastic and Oral Surgery established in Philadelphia by the Surgeon General, U. S. A. Prepared at the suggestion of the Subsection on Plastic and Oral Surgery Connected with the Office of the Surgeon General. Pp. 442, illustrated. Price \$4.50. Wm. Wood & Co., New York, 1919.

"The Sign of
the Rx Pharmacy"

Accurate Diagnosis First

No industrial hospital is complete without the most modern facilities for diagnosis. They must be ever ready for the immediate attention a patient's case demands.

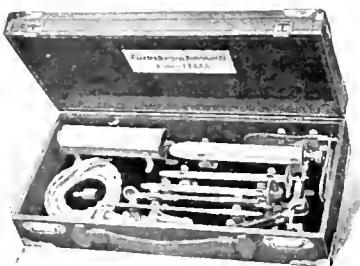

Diagnosis directs the course of treatment and can only be accomplished by the most advanced and approved aids.

For just such attention by the industrial or municipal physician our

MODERN DIAGNOSTIC OUTFIT

is arranged. It contains all the instruments most generally needed in urgent cases.

Others will be substituted if desired. Stamp "E. S. I. CO." is guaranty of our manufacture.

This outfit weighs but 4½ pounds. All instruments can be operated by our battery with adapter or upon direct or alternating current by means of our controller.

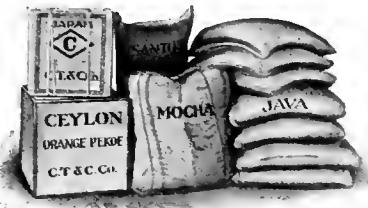

Illustrated catalogue sent upon request.

Electro Surgical Instrument Co.
ROCHESTER, N. Y.

A collage of historical Simmons Bed advertisements. The top left features a large ad for 'SIMMONS BEDS' with the tagline 'Built for Sleep'. Below it is a smaller ad with the headline 'Perhaps your Bed Doesn't Suit You so well as You Think...'. To the right is another 'SIMMONS BEDS' ad with the tagline 'Doctor Says about Simmons Beds'. Further down is an ad with the headline 'How Much Sleep do You Need?'. The bottom right corner contains the text 'SIMMONS COMPANY KENOSHA, WISCONSIN'.

Remember ARISTON COFFEE-CEREAL BLENDS

C are not Coffee Substitutes

THEY are combinations of good coffees and carefully prepared cereals. They retain all the cup quality of straight coffee, with nourishment added. They effect a saving of several cents per pound, and are highly economical in these days of increased coffee prices.

Ariston Coffee-Cereal Blends are more than half coffee, blended with a small percentage of chicory and the most nutritious of cereals, roasted and prepared especially for this use in our Brosia plant.

They satisfy perfectly the coffee taste, while adding a nourishment of real value. They reduce the caffeine factor and the tendencies—in some people—to nervousness and wakefulness.

They are of especial value for use by persons who are affected unfavorably by strong coffee and to whom weak coffee and coffee substitutes are neither palatable nor satisfactory.

Ariston Coffee-Cereal Blends Are Food Beverages

- a. Satisfactory to the Coffee Lover.
- b. Of Great Nutritive Value.
- c. At a Substantial Price Saving.

Made in five blends, differing only in the grade of the coffee component:

Blend No. 1—\$0.32 per pound
Blend No. 2— .30 per pound
Blend No. 3— .28 per pound
Blend No. 4— .26 per pound
Blend No. 5— .24 per pound

On a minimum trial order of 100 pounds we prepay the freight, and bill at 60 days to allow thorough test. We guarantee both quality and satisfaction, the goods being returnable at our expense if they fail for any reason to please you.

In ordering, please state whether the grinding shall be "Medium," for coffee pot, or "Fine," for percolator or urn.

Mail us the coupon, with blend number, grinding instructions and shipping address filled in.

That puts it up to us

DISBAND GENERAL MEDICAL BOARD

The General Medical Board and Medical Section of the Council of National Defense ceased its existence on April 1st. Dr. Franklin Martin, chairman of the Medical Board, in a letter to the seventy-five physicians constituting the Board set forth the achievements which had been accomplished. Secretary of War Newton D. Baker expressed the appreciation of the government for the service rendered.

Secretary Baker, in his letter, said:

"While it would be invidious to make any appraisal of the work of your board in comparison with that of any other agency organized in the emergency, I need not, I know, assure you that the government appreciates deeply and genuinely the great and essential contribution which has been made by the Medical Board in the mobilization of the civilian profession, its classification as to specialties and fitness, and in the preparation and organization of information which would enable the Department to secure from the manufacturers of the country the vitally necessary instruments and supplies for the medical care and attention of our men in the field."

Dr. Martin said:

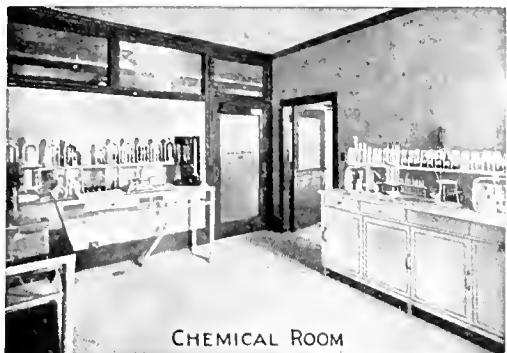

"Not until the history of our part in the great war is written will the people realize the important role the medical profession of the United States played in making our country a deciding factor in winning the war. Do you realize that in the year before our entry into the conflict the commissioned officers in the medical departments of the army and the navy numbered less than five hundred in each service and that practically 40,000 civilian doctors had been added to these two corps by the time hostilities had ceased? When the story is told of the enrollment of these thousands of doctors, it must give the largest credit to our many state and county committees who labored so patriotically and continuously to carry out the recommendations of the organization under which they worked, the Council of National Defense, and thus aided the administrative departments of the Surgeons General of the army, the navy, the Public Health Service, and the Provost Marshal General.

"The work of these committees under the direction of the General Medical Board had to do with activities of which the following is a brief summary: Recruiting medical officers; standardization of medical and surgical supplies; cooperation in controlling venereal diseases; mobilizing five thousand dental surgeons; establishing committees on hygiene, sanitation, general surgery, orthopedic surgery, ophthalmology, otology, rhinology, and laryngology, general medicine, nursing, women physicians, and medical schools; organizing medical advisory boards; the study of industrial medicine; securing through legislation increased rank for reserve medical officers; and finally, individual classification of the members of the profession through the medium of the Volunteer Medical Service Corps.

"I want you to know that those of us who have had the responsibility of organizing and enrolling the medical profession and resources appreciate the value of your work and thank you for it from the bottom of our hearts. This includes the Secretary of War who presides over the Council of National Defense, the Secretary of the Navy who is one of its members, and the President of the United States, who appointed the Council and on two occasions has said, in speaking of our state and county committees: 'Will you not be kind enough to convey to them a message of sincere appreciation from me of their services as authorized governmental agencies?'

Ohio Medical Society Discusses Health Insurance

The Ohio Medical Society will devote a special session to the subject of health insurance, at its annual meeting, May 6, 1919. The speakers will be Lee K. Frankel, third vice president of the Metropolitan Life Insurance Company; Otto P. Geier, M.D., of Cincinnati, chief physician of the Cincinnati Milling Machine Company; William Gale Curtis, president of the National Casualty Company, Detroit, and John A. Lapp, managing editor of MODERN MEDICINE. A majority of the Ohio Commission on Health and Old Age Insurance reported in favor of compulsory health insurance.

CHEMICAL ROOM

A LABORATORY SERVICE

for

The Industrial Physician

and

The Public Service Official

as well as

For the Private Practitioner

THE CHICAGO LABORATORY

The personnel and equipment of the Chicago Laboratory insures expert findings in all tests whether chemical or analytical in the shortest possible time consistent with high-grade work.

Containers for collections and specimens will be furnished gratis upon request, and if you do not have our Fee Table write now for it.

We Make Bran Likable

As doctors requested.

Most sorts of bran food have been uninviting.

We hide the flake bran in flavorful flakes of wheat. And the dish is one which everyone enjoys.

We also hide it in a flour, so some bran dainty can be served with every meal.

Now in countless homes, by doctors' advice, Pettijohn's is a staple.

Pettijohn's

Rolled Wheat—25% Bran

A breakfast dainty whose flavorful flakes hide 25 per cent of bran.

Also Pettijohn's Flour—75 per cent fine patent flour, 25 per cent bran. Use like Graham flour in any recipe.

MILWAUKEE HAS NUTRITION CLINIC

In a neighborhood of home-owners and workingmen's families in Milwaukee, Wis., a nutrition clinic is being conducted under the direction of the Wisconsin Anti-Tuberculosis Association. A survey will be made of the results gained. For the purpose of the survey the work of the clinic has been divided into four groups—school service, medical service, dietetic service, and home service. Among 665 children examined in a preliminary survey were found 130 who showed undernourishment to the extent of 10 per cent or more. Their ages varied from six to fifteen years. The proportion of girls was 24 per cent of a total of 304, and of the boys, 16.1 per cent of a total of 364 pupils.

INDUSTRIAL PHYSICIANS IN CONFERENCE

The Industrial Physicians and Surgeons of Pennsylvania considered the question of a more active cooperation with state health bureaus and health officials during the eighth conference of the organization, which took place last month at Philadelphia. A paper on the subject of "Carbon Monoxide Poisoning—Its Prevention and Treatment," presented by Colonel A. J. Lanza, of the United States Public Health Service, appears in this issue of MODERN MEDICINE. Dr. Alice Hamilton, of the Bureau of Labor Statistics, spoke on "Health Hazards in the Manufacture of Dyestuffs." "Health Insurance—Its Advantages and Disadvantages" was discussed by John A. Lapp, formerly director of the Ohio Old Age and Insurance Commission, and Frederick L. Hoffman, Prudential Insurance Company.

RESIDENT PHYSICIANS FOR FACTORIES

The presence of a resident physician at every large industrial plant, within easy access of the working force, was deemed a necessary condition in factory management by the delegates in attendance at a "Safety First" Congress which took place in Cincinnati, January 10 and 11, 1919. The Ohio Industrial Commission conducted the meeting at the request of large employers in that city. Its purpose was the study of accident prevention. Smaller plants, it was urged, should retain a competent assistant who could render first aid and summon a physician when needed, if it were not practical to provide a resident physician. The plan is believed to contain economic and social values that will help employers solve some of their problems. Several physicians representing industrial organizations and civic bodies were in attendance.

IN THE HEALTH BULLETINS

The February issue of *Health News*, the monthly bulletin of the State Department of Health of New York, prints a series of articles on the problems of health centers.

The February *Bulletin of the Minnesota Health Association* contains brief articles on public health nursing, care of tuberculosis, ventilation, venereal disease, and cancer prevention.

The *Bulletin of the West Virginia State Department of Health* for January discusses child welfare in a number of practical articles, the prevention of pneumonia, and the work of the hygienic laboratory at Charleston.

The monthly *Bulletin of the Department of Public Health and Charities, City of Philadelphia*, for February, discusses the relation of the movies to the health of school children, eyestrain, mortality incident to pregnancy, and an experience with the Schick test and toxin-antitoxin mixture in industrial schools.

NOTES AND COMMENT

HEALTH AND RECONSTRUCTION

PROGRAMS of reconstruction which have been issued by the various organizations other than health and medical societies give scant attention to the subject of health in social and industrial reconstruction. This is a strange omission when we consider the importance which has been attached to health as an element in the nation's efficiency in war and the interest which has been developed in carrying forward programs of health into peace times.

The program of reconstruction of the Chamber of Commerce of the United States adopted at Atlantic City in December, 1918, did not even mention health as an element in industrial management or industrial efficiency. The statement of principles of industrial relations submitted for consideration to the membership of the organization in April, 1919, does not touch in any way upon the subject. The nearest approach is contained in the statement that "industrial enterprise as a source of livelihood for both employer and employee should be so conducted that due consideration is given to the situation of all persons dependent upon it." This statement might be stretched to cover provision for industrial health service.

Strangely enough, the program of the American Federation of Labor does not deal with the subject of health of workers except in so far as that subject is included under the general betterment provisions for shorter hours and better wages.

The program of social reconstruction issued by the National Catholic War Council is one which gives important recognition to health as an ele-

ment in reconstruction. Besides discussing the relationship of wages, housing, and cost of living to decent standards of life, the following express declaration is made:

"The establishment and maintenance of municipal health inspection in all schools, public and private, is now pretty generally recognized as of great importance and benefit. Municipal clinics where the poorer classes could obtain the advantage of medical treatment by specialists at a reasonable cost would likewise seem to have become a necessity. A vast amount of unnecessary sickness and suffering exists among the poor and the lower middle classes because they cannot afford the advantages of any other treatment except that provided by the general practitioner. The service of these clinics should be given gratis only to those who cannot afford to pay."

In addition, the Council also declares for insurance against illness, invalidity, unemployment, and old age as a substitute for the time being until wages shall have reached a point "high enough to make possible that amount of saving which is necessary to protect the worker and his family against sickness, accident, invalidity, and old age."

There is, of course, due recognition given in programs and announcements of social service organizations, and health and medical societies of the necessity for the expansion of all types of health service. The figures of the draft, showing that large numbers were totally incapacitated for any service and, as stated by Major General Leonard Wood in this issue of MODERN MEDICINE, that fully 50 per cent of the youth of the country were unable to stand field service, have aroused the

country to the need of very definite and specific action to provide against such a contingency in the future. Statistics showing that from 50 to 75 per cent of all school children have some defect which is curable have given proper emphasis to the need of infant welfare work, pre-school health work, and adequate supervision of the health of children in all schools. Legislation is pending in Congress for Federal assistance to physical education and other types of health service, including medical examination and supervision of school children. These recommendations contrast sharply with the failure of groups outside the direct field of health and social service to speak clearly and explicitly in favor of an adequate health system as a part of the program of national reconstruction.

MEDICAL SERVICE UNDER WORKMEN'S COMPENSATION

THE state of North Dakota, the thirty-ninth state to adopt a Workmen's Compensation Act, declares as a fundamental principle that it is "the intent of this act to restore to industry those injured in the course of employment. The bureau shall accordingly assist industrial cripples to obtain appropriate training, education, and employment, and may cooperate with the Federal Board of Vocational Education for this purpose." This declaration follows the provision that "immediately after an injury sustained by an employee, and during the resulting period of disability, the North Dakota Workmen's Compensation Fund shall furnish to such employee such medical, surgical, and hospital service and supplies as the nature of the injury may require."

These provisions are in marked contrast with the laws of a number of states. Of the thirty-eight states and three territories which previously have had workmen's compensation laws, four states give no medical benefits whatever; nine states give medical care for fourteen days; three states give medical care for three weeks; six states which have a time limit have also a money limit ranging from \$25.00 to \$200.00.

The most liberal provision is that found in the United States compensation law which provides for reasonable medical, surgical, and hospital service and supplies, without limit as to time or amount and, if necessary, transportation of injured employee to place where he can be properly treated. This is in marked contrast with a law such as that of Pennsylvania which provides for reasonable medical and hospital expenses for fourteen days, but not to exceed \$25.00 unless a major operation is necessary, when the amount is limited to \$75.00.

It is fortunate that the practical point of view is coming to prevail in this matter, and that medical care is being recognized more and more in the new compensation laws and is being extended in amendments to old laws. Employers are at last recognizing that it pays to restore men by means of the best medical care rather than to pay compensation during long terms of disability.

The treatment of every minor accident has been found to be profitable. It costs little and may save hundreds of dollars compensation by preventing infection.

The importance of medical service was well set forth by Oliver J. Fay, M.D., of Des Moines, Ia., in the *Journal of the Iowa State Medical Society*. Dr. Fay said:

"The limitation of the liability of the employer for medical, surgical, and hospital service is a weak link in the compensation service from whatever angle considered, whether the limitation be to a given sum, as in Iowa, or a period of thirty, sixty, or ninety days as in some other states. A large majority of injuries are minor injuries in which the liability of the employer is limited by the character of the injury to less than the minimum established by law. Any case which is not so limited is of so serious a nature that not only the interests of the employee, and even those of the employer, but also those of the commonwealth are jeopardized by any such limitation.

"One of the basic lessons of the present war has been that no system of pensions, however generous, is adequate. No medical care which stops short of restoration to the greatest possible usefulness is satisfactory where our injured soldiers are concerned, and what is true of our National army is equally true of our great industrial army, whose casualty list is not limited by the duration of the war, but must continue as long as the wheels of industry turn. This may be social medicine, but certainly it is the only measure acceptable to our vaunted American efficiency. The vital issue in industrial medicine cannot remain the determination of the percentage of compensation to be given for a given injury to the hand; it must stop short of nothing less than the restoration of that hand to the greatest degree of usefulness possible, and compensation when given will then be based upon the functional and not upon the anatomical loss. Society, which reaps a harvest of some thousand dollars from the industrial life of each laboring man, cannot long countenance the wasteful system of annually allowing a considerable number of her laborers to be made mendicants by the operation of faulty compensation laws.

"From the lessons which we are now learning

from this great war, it is estimated that six months is the average time required for industrial reconstruction and rehabilitation of the man with a major injury. It may be argued that so long a stay under the necessarily expensive roof of a reconstruction hospital would be too heavy an expense for our insurance companies, and, ultimately, the employer. We are not primarily concerned with the return of a given dividend to any insurance company, and, since it is the State which is most vitally interested in rehabilitation of the injured workingman, it is the State which must take over the problem when the employer fails of its solution. There is at this time a bill before Congress providing for the rehabilitation of the injured in the industrial army of this country, the expense of such reconstruction work to be shared equally by the Federal and the State governments. This work would call for men with special training and qualifications; and an army of medical men are now receiving this special training in the great school of war. When their task of returning the maimed soldier to a life of useful activity is completed, the great industrial army may well claim their services."

The future development of compensation laws almost certainly will be in the direction of physical and vocational rehabilitation. The primary interest which society takes in compensation is the restoration of men to working capacity equal, as nearly as possible, to that which they enjoyed before the accident occurred. Physicians and educators must cooperate to restore men to working capacity in gainful occupations and thereby salvage as much of human power as possible.

THE SEVERITY OF SICKNESS

NUMEROUS studies have been made during the past year to determine the extent of sickness among the workers and the general population. There are summarized in this issue studies showing that about 20 per cent of the workers suffer a disabling sickness each year lasting more than seven days. Approximately 6,000,000 workers are, therefore, annually, disabled. The average length of each disability is about 35 days. Of the 6,000,000 who are sick, it appears from the comprehensive data of the surveys that 65 per cent, or 3,900,000, are sick for less than four weeks; 19.7 per cent, or 1,182,000, are sick from four to eight weeks; 6 per cent, or 360,000, are sick from eight to twelve weeks; 3 per cent, or 180,000, are sick for more than six months; and 1.3 per cent, or 78,000, are sick for more than a year.

These figures do not take account of the chronically sick, and the defectives. They relate

to employed persons who are working at the beginning of the year. If we add those who have been sick for more than a year, we find that probably a quarter of a million people are completely incapacitated at all times. On the average there are also 700,000, or nearly 2.5 per cent of all workers, who are suffering from a disabling sickness every working day, while another half of one per cent are away from work each day on account of trivial disabilities.

The losses to the men who are sick are very serious, especially when the disability extends beyond thirty days. A large part of those who are sick for long periods are driven to economic distress or dependency. The losses resulting to society appear in their true seriousness in a time of stress such as the emergency caused by the war needs for production. The number of ships that could be built, or the number of tons of coal that could be mined with the 300,000,000 days of labor which is now lost, can be readily determined. The saving of merely 25 per cent of the loss would bulk large in the wealth of the nation.

THE RETURNING DOCTOR

THREE is much speculation as to the changes in practice of medicine as a result of war service. Will the doctors go back to general practice? Will they lean toward public health activities? Will they desire rather to take up preventive work in factories and schools than to resume general or special practice? Has state medicine been promoted by the employment of large numbers of physicians on salaries in the public service?

These are some of the questions which are being asked. They are all receiving affirmative answers by the results of demobilization, to date. What the final tendency will be cannot be clearly observed for some time. That there will be changes is certain. Probably one of those changes, particularly in rural districts, will be in the direction of group practice.

The army doctors have been practising group medicine for two years. They have been doing team work. Specialists were available for every case which needed their services as a part of the regular routine. Diagnosis was made by cooperation among as many doctors as were necessary to make it complete. There was very little individual work. The men worked rather in teams. Preventive medicine was practised on a large scale and all of the doctors took part in it. There were hospitals to take care of the disabled, but the main object was to keep the men well and physically fit.

Many doctors undoubtedly received a new view of the practice of medicine, and many un-

doubtedly lost their desire for individualistic practice. They will, when they go back to their former fields of activity, desire to work more in teams and to have better facilities than heretofore. The rural doctor particularly will desire to have some type of group practice with facilities to take care of the sick in the rural regions. Army practice has shown the way for the development of group diagnosis and treatment, and the physicians who have worked long enough in the army to get the new point of view will not be satisfied to practise medicine, in the country, at least, without having within reach more complete diagnostic facilities and accessible provision for the care of the sick, together with means of transportation. Experiments in the extension of medical service into rural districts through rural hospitals, as in Canada and in some parts of this country, have pointed the way for an enlarged development which the experience of the returning doctors will make easier of accomplishment.

TO MAKE HEALTH INFORMATION FUNCTION

MEDICAL science laboriously compiles its pages of data and knowledge. The librarian takes the works of each individual in books and magazines, and puts them on the library shelves. There the information remains, untouched and unused, too often. There is an abundant harvest of health information every season. But the vast bulk of published matter does not serve the medical profession or the public in the fullest measure, because it is so often put in storage even while the ink is wet on the pages.

Science has been prolific in discovering preventive methods for the control and destruction of disease, and men of science have been painstaking in publishing the facts. Resting on the shelves of libraries there is sufficient knowledge of medical science to reduce materially the death rate and prevent the ravages of disease. Yet only a part of the results of research has been made to function for the public welfare. The problem now is the call of duty in translating this accrued information into action. The responsibility of collecting and interpreting data of health to the people, and expressing it to them in their own manner of speech, rests upon the physician. The exercise of this responsibility of the physician is important because there must be wise separation of quackery from science.

In performing this duty the medical profession encounters two difficulties. It must keep in touch with the progress of medical science and it must

be expert in publicity. It must gather the facts and it must sell the product—health—to the public. Neither of these difficulties can be overcome except by organization. No single physician can hope to keep abreast of all phases of medical progress. A dozen physicians could scarcely do that except by devoting more time than can be spared from active practice. But a body of specialists, organized with research facilities in medical literature, which sifts the current scientific publications and delves into the old ones, could mobilize efficiently all that is essential of the world's knowledge of medicine. Public health departments equipped with such facilities could succeed in mobilizing health knowledge and experience for the benefit alike of doctors and laymen.

The next problem is to make the knowledge so mobilized work effectively in the treatment of disease and the preservation of health. Stores of medical knowledge do little good in libraries, or even in the heads of men, if patients are not cured or protected by it. Science pursues its discoveries not to accumulate knowledge but to promote welfare. Physicians acquire and accumulate medical knowledge solely for use in aid of men. Public health officers are engaged with the physician in the attempt to put medical science into practice. Success in selling the knowledge of health will be a powerful stimulus to the physicians in accumulation and to the scientists in discovery.

Students and masters of the science of medicine and therapeutics address their written discussions and observations to one another—seldom to the layman. The usual book or article on medical topics is written for medical men and read by medical men. How readily it is possible to translate this same information and knowledge into language adapted to popular tastes in reading is well illustrated in the departments of certain large newspapers in cities like New York, Chicago, Philadelphia, and Boston, in which health questions are discussed by physicians, who edit and write the departments for the layman.

These columns of health news are read by thousands daily. They furnish an excellent example of the educational possibilities of the press. More literature on medical subjects in the style designed for lay readers is needed. There could be no more opportune time than the present period of social and industrial reconstruction for instituting a widely organized campaign for health. A splendid opportunity offers itself. New groups should be formed in the medical profession, coördinate with those now existing, and new channels opened up for extending the benefits of medical science into all corners of the land.

PHYSICAL EDUCATION AND NATIONAL GROWTH

BY LEONARD WOOD, M.D., MAJOR GENERAL, UNITED STATES ARMY

THE physical condition of the young manhood of the nation, as brought to our attention by the draft, is cause for great anxiety. Roughly speaking, 70 per cent of the men who were of military age and who were examined by the draft boards for military service were sent forward to the training camps for induction into the service, and 30 per cent were rejected as unfit. This was after all the exemptions had been made for family, business, and other reasons.

Of the 70 per cent who were sent to the training camps, 8 per cent were rejected as unfit for military service, and this under standards as to physical requirements which were much lower than those in effect in the Regular Army in time of peace; that is to say, men were taken with minor defects which would cause their rejection by the Regular Army under peace time requirements.

Many of the physical defects were of a character which could have been easily corrected in early youth through proper training and exercise. Others could have been very much benefited. Flat chests, spinal curvatures and deformities, flat feet, wretched muscular development, defective teeth, slow coordination of mind and muscle were common. And this among the 70 per cent who were sent to us as presumably fit for service. What the condition of the remaining 30 per cent was can readily be imagined.

Again, many men were exempted as obviously physically unfit, and were not brought before the boards for physical examination. It is safe to say that 50 per cent of our men were unfit for field service in war. This is bad enough from the military standpoint, but it is even more serious from the standpoint of industrial efficiency.

Among the men from the South there was a very large proportion of men with hookworm, with its attendant anemia and sluggishness of mind and muscle. Indeed, the entire situation was one which indicated the need of much broader and deeper interest on the part of the State in

WHAT THE DRAFT HAS TAUGHT

We must wake up and pay much more attention to the physical and moral development of the youth of the country.

We are losing a large portion of our men from a standpoint of military efficiency by physical defects that could be corrected in early youth by proper training.

We are subjected to enormous wastage from the standpoint of economic and industrial efficiency.

These are losses which the Nation can ill afford, in view of the coming contest for industrial supremacy.

point. Carelessness brought out very forcibly the necessity of more careful teaching in matters that have to do with personal hygiene.

Certainly these facts indicate very clearly that we must wake up and pay much more attention to the physical and moral development of the youth of the country; that we are losing a large portion of our men from a standpoint of military efficiency, and are subjected to enormous wastage from the standpoint of economic and industrial efficiency. These are losses which the Nation can ill afford, in view of the coming contest for industrial supremacy.

Then again, if we want sound children we must have sound parents. To insure this end much more thorough and intelligent methods are required in the education of our youth. Much has been done. Much more must be done.

We must have thorough and careful physical supervision of our children in the schools, beginning with early youth. We must carry this work through systematically. It is of vital importance to the nation. With the physical training must go careful moral training.

Another powerful agency in correcting existing physical defects will be found in universal training for national service. This training will include rigid physical supervision and intelligent effort to build up poor physiques and to correct physical deficiencies. This, however, will only reach the boys and young men. Our physical training must be broad enough to reach the girls and young women of the land.

the welfare of its youth, the establishment of measures looking to the building up of physical training and general sanitary supervision in public schools and in all places where the youth come under the supervision and control of the State. There was also a large percentage of vice diseases, indicating the importance of emphasizing the dangers to which youth is subjected, and the need of more thorough instruction on this

GROUP MEDICINE

BY A. J. BARKER SAVAGE, M.D., SUPERINTENDENT BROAD STREET HOSPITAL, NEW YORK CITY; CONSULTING SUPERINTENDENT, NEW YORK MEDICAL COLLEGE AND HOSPITAL FOR WOMEN, NEW YORK, AND THE HARBOR HOSPITAL, BROOKLYN, N. Y.

THREE is but little special literature on the subject of group medicine because of its relative newness. Cooperation in medical practice is by no means new, and group medicine, if we regard the Mayo institute as an example, is no longer novel. As a matter of fact, as we shall develop later, the term to-day really implies the result of a movement begun on the Pacific slope as recently as 1915.¹ This is, of course,

another way of saying that the term "group medicine" may be understood in several different ways, which will be elucidated later. From the California point of view, group medicine had a very simple origin. Information had slowly accumulated that in all general hospitals many avoidable diagnostic blunders were continually made, and group medicine was intended to prevent this catastrophic state of affairs. Group medicine was essentially group diagnosis. In the Mayo institute, one internist makes the diagnosis and refers the patient to the operating specialist, a method which is neither group diagnosis nor group treatment. The same procedure is seen in any dispensary when the clinical clerk, after looking over a patient, refers him to the proper class. This entire matter will be threshed out in full.

Some authorities see in group practice of any sort the natural tendency of an art like medicine, once split up

THE PRICE OF DIVIDED EFFORT

The sharply defined division of the several fields of public health endeavor has been open to serious objection.

The separation results in over-lapping efforts in some directions, while other phases of health work get scant attention.

In consequence of effort duplicated, the expense for administration of health activities is increased proportionately.

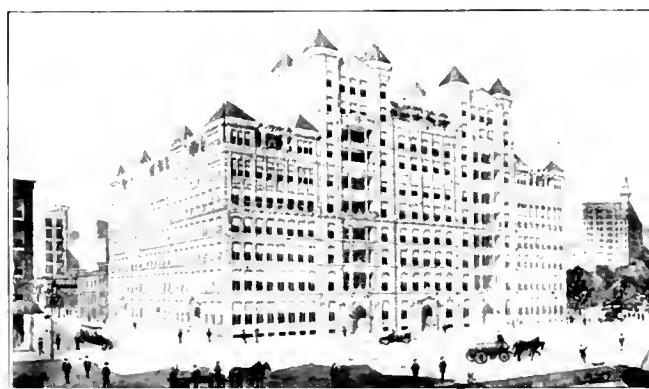

To promote real efficiency there is needed a practicable method for coordinating the work of health and social agencies.

into independent specialties, to undergo integration by cooperation of the disunited forces. All has depended on the creation of technical subdivisions of practice and of the attitude, finally reached by the profession as a whole, that specialism, in so far as it connotes great technical skill in diagnosis and treatment, is not commercial and charlatan but legitimate and indispensable. We have said that there is little

literature of group medicine. Let us first define this term as we understand it. First, however, it will be necessary to outline the condition of affairs when group practice of medicine is altogether absent.

If an internist examines a private patient and finds no organic affection but a highly developed nervousness and suggestibility, he will be very willing to transfer the patient to a neurologist. The latter in turn may find reason to believe that

the nervous symptoms are at bottom dependent on some slight structural anomaly in some portion of the body. Perhaps he will think the mischief is of urogenital origin. In any case, treatment directed against such mischief may have a suggestive value. It has recently been learned that much invalidism and imitation of disease can be traced to stricture of the ureter. A score of similar possibilities exist where trivial lesions in quite different parts of the body

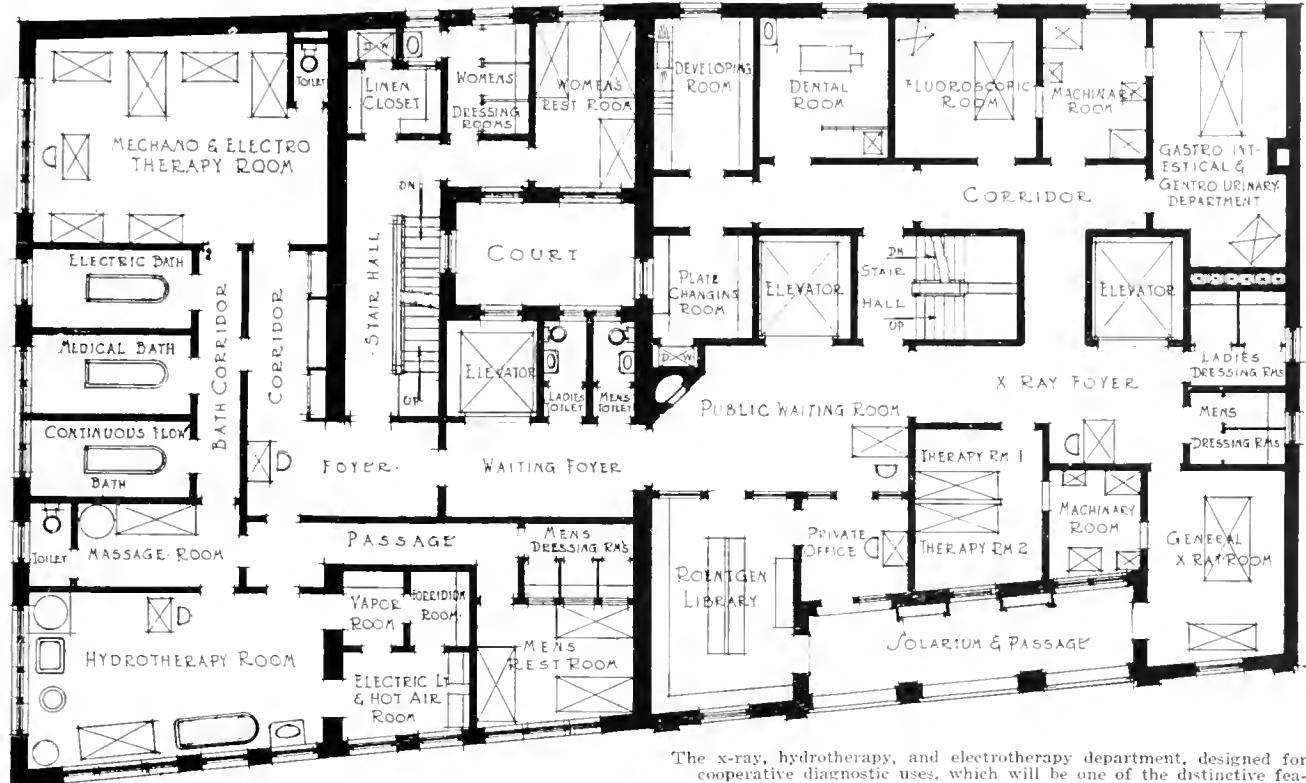

The Broad Street Hospital, New York City, overlooking the waterfront, as it will appear upon completion of the new wings to the present building. Its frontage permits of an outlook over the towns that lie on the opposite shores of the North and Hudson Rivers, and a view of the Statue of Liberty. It is here that a plan of cooperative, interdepartmental medicine is being developed. Owing to the proximity of the hospital to the waterfront, numbers of seamen and nondescripts come to the institution, some of them suffering from rare diseases and conditions contracted in distant localities. It is proposed to combine the examining and diagnostic facilities with the therapeutic functions of the hospital so that a patient who requires special examinations can be brought to the hospital and for one, fixed, moderate fee have the expert services of all of the specialists, and, after consultation, be given the best conjoined advice as to treatment.

render men and women invalids, and only as a result of a complete diagnostic examination can this mischief be found and corrected. When found, it may have to do with an anomaly of refraction or badly fitting glasses, with an infection of a nasal sinus, or with an infected tooth-root, and so on throughout the whole organism.

and practicability of a non-institutional federation of private practitioners acting as a diagnostic and therapeutic group. This movement we believe to be quite out of consideration in this connection. We may refer to it later.

If, however, there is little literature directly bearing on our subject, we are automatically re-

The x-ray, hydrotherapy, and electrotherapy department, designed for cooperative diagnostic uses, which will be one of the distinctive features of the proposed additions to the Broad Street Hospital, New York City. (William Neal Smith, architect.)

Proper Treatment Begun at Once

Traveling from one specialist to another entails much waste of time—for probably every practitioner consulted will reach his conclusion only after his own remedies have failed entirely—and necessary expense in fees, drug bills, and perhaps trips to health resorts and expensive apparatus. Could the patient be examined by a number of competent men at one or a few sessions, a diagnosis could often be made at once and the proper treatment instituted. The expense, whatever it might be, would be only a fraction of what it often is.

Group medicine is therefore an economic feature of medical practice intended primarily to benefit the patient; and incidentally to raise the status of the medical profession by making it immune to the frequent charge that people are sent from one specialist to another until their funds are exhausted.

In stating that as yet this subject has little literature, we pass over the fact that considerable has been written concerning the possibility

minded of the Mayos whenever it is mentioned. Most practitioners would call this institute the one supreme example of group practice. In a sense this may be the truth, but there are important distinctions to be made.

Personnel of the Mayo Group

One thinks of a group federation as a democratic association on purely equal terms of men of equal age, prestige, and capacity. The Mayo brothers, however, do not conduct their establishment on any such lines. They are purely autocratic and their group men have been as far as possible kinsmen and protégés who have taken training for special practice. The policy of commercial houses has been followed in this respect, and the group men resemble heads of departments. Able and skillful as they are in their special fields, they are not wholly responsible in their own persons, nor can they compare either in income or prestige with the independent practitioners in their own fields. One could easily conjure up in imagination a group of these men

working together who might even surpass the fine work of the Mayos or the excellent accomplishment of the great hospitals of Chicago.

There are, however, some advantages about an autoeratic establishment, for in matters of diagnosis there must be someone to stand for the final and complete diagnostic expression of the disease and some master mind at times to set the course of treatment.

From quite another aspect, the Mayo establishment may be lacking in an essential of group treatment, to wit: it is purely a surgical institute. The advantages here are quite obvious although they are not such as to exclude absolutely medical cases. The central thing about a surgical institution is the operation, which alone justifies the large fees paid. Every patient visits the hospital for a possible operation. If the case is inoperable he goes home, and if operable, he goes home after convalescence. Thus there is a complete and rapid rotation of cases throughout. Yet a complete system of group treatment should include medical cases as well, limited naturally to acute and subacute affections. The chronic ease belongs, of course, to the sanatorium. The victims of acute disease usually need to be under surgical supervision from the start.

For instance, take the example of a lady with typhoid in one of our leading hospitals. The visiting physician overlooked completely a beginning infection of a rib, and the patient was sent home in a condition which was followed by long invalidism and an operation of severe character. Even a cursory examination by the visiting surgeon would have disclosed the complication. In hospital practice it is the custom to wait for developments and then transfer to the surgical service, but far better is a surgical control from the start. Many a patient controlled from all angles would leave the hospital cured who now leaves partly cured, to return later. There are now so many borderline diseases of both medical and surgical character that it is difficult to understand how they are in one service to the exclusion of the other.

Group Practice Differs From Dispensary Plan

While the expression "group medicine" and "teamwork" are new enough, the claim might be made that the practice is by no means new. Does not a large outdoor department of a hospital or a special dispensary like those which have flourished for years embody the same idea? The resemblance here is purely illusional. A number of specialists are indeed gathered in one building at the same time, and cases are made the subject of consultations, but the vast amount of the work is

individual; the different men serve on certain days only, the makeup of the men is constantly changing from day to day, the equipment is scanty, different specialists share the same rooms on different days, only a little time can be devoted to the individual ease, and the patients as a rule present the same monotony of symptoms so that really interesting and obscure cases are rare. When a patient is transferred from one class to another, it is often rather to be rid of him than to give him the benefit of a consultation. The prime end of dispensary practice seems to be to satisfy the patient with a prescription or application to relieve some symptom, or to do a great amount of good to the community as a whole with the smallest outlay of time and expense. It is very unlikely that group practice would ever have evolved on a dispensary basis. The better and more complete the service, the greater the number of patients with purely routine maladies which call for stereotyped treatment. When an obscure case does appear, the patient will probably receive some attention; he may go before a medical society of experts as an exhibit and so in time secure the benefits of group diagnosis. These medical society cases naturally only go before one class of experts at first but they may be referred to others and so on until the mystery which they present is solved.

Abuses in Transfer of Cases

The subject of a sort of tandem teamwork among private practitioners has received considerable attention as a custom to benefit the patient. As we understand it, it has been tried to some extent and condemned as inefficient and impracticable. The custom of passing a patient along could itself be made the subject of a paper. The motives vary much. One practitioner may be under obligations to throw work to a relative, a protégé, or the son of an old colleague. Many specialists will frankly admit that their success was due to the powerful support of a few friends at the outset. General practitioners have their favorite specialists for consultation. A much more ample motivation is seen in the cooperation of the specialists of a medical college. To secure a professorship in such an institution usually means the loyal support of the colleagues. Even if a man is personally unpopular with his colleagues, they will hardly refuse some recognition. In the absence of college affiliations, hospital affiliations serve the same purpose. The continuous transfer of cases, however, is not in the interest of the patient or his pocketbook. In fact, it has formed a sort of abuse which group medicine has to correct.

The transfer of cases among practitioners, gen-

eral and special, is often of quite a different type. For one or another reason, the patient has become a burden to his doctor who gets rid of him by sending him to a colleague, who will very likely find that the man's funds have given out or that he is a hypochondriac nuisance or pest. Needless to say, the practitioner does not send such cases to his cronies without a private explanation. Instead he may send them to strangers or colleagues whom he secretly dislikes. Would-be specialists may be made the butt of grim jokes, as when a case of corns or bunions is referred to an orthopedist.

Public Exaggerates the Faults

The public is quite aware of the abuses of the transfer system and is inclined to exaggerate them and to doubt men who are really acting in the best of faith for the patient's own interest. Although patients are so often referred to colleagues, it is safe to state that in a majority of cases they do not go at all or do not go until time has elapsed. In a tandem method of cooperation or teamwork, the objection which would first be apparent is the contrariness of the patient about being transferred. It would mean delay in the waiting room and time spent in transit. Often a sort of innate repugnance makes the invention of excuses easy. It is possible that the custom of erecting special buildings for physicians has been favorable for the transfer of cases between colleagues, but, so far as we know, no teamwork activities have been developed on this basis.

Group medicine naturally suggests the hospital as the only practicable place for teamwork, and, as we shall show later, legitimate and unobjectionable teamwork first began and first made good in hospitals. On paper most large hospitals have for many years possessed consulting staffs, but, in most instances, these are seldom called upon—perhaps a few times annually to justify the appointment. But when even the visiting physicians and surgeons show such feeble cooperation, we cannot expect to see any feeble beginnings of group medicine under the old regime. Physicians and surgeons are often rivals in the great field of borderline cases; each class claims them and each accuses the other should the case end badly. Instead of neutral wards with both physicians and surgeons in daily consultation, we find the borderland case in full charge of one man who has absolute control of the case and sole right to summon counsel.

A particularly disagreeable feature of modern hospital activities shows at once the need of teamwork and of reform in hospital administration. We refer to the custom of charging a patient with-

out his knowledge or consent with extra fees for x-rays and laboratory work. The patient is usually poor and has raised all he could obtain for the known charges for ward treatment. The items for special service are charged at full rates and the bill is thrust upon the patient while he is still under treatment. In vain he states that his consent was not obtained for his \$25.00 x-ray fee and his \$5.00 blood and urine analysis. He is abused verbally and given the impression that he cannot leave the building until these extras are paid for. These threats are only verbal and apparently never carried out. Doubtless the policy is pursued only with those suspected of having misrepresented their finances. However, many worthy poor have been inexpressibly shocked and worried by these bills and at a time when ill prepared for such treatment. They are told at their discharge that the amount will stand in their name on the hospital books, and this custom is a cause of renewed complaint. Doubtless these bills are often compromised at a low figure. The only answer ever made in defense of these customs is the ever-present need of money without which the hospital would have to cease its good work altogether. The high-handed and arbitrary procedures doubtless help mightily to cut down the annual budget, and, if exposed, would at least stimulate increased contributions from the well-to-do philanthropists.

Why Group Treatment Must Come

The very existence of such customs shows the need of an institution for the practice of group medicine. The patients cannot be tested intelligently without group practice, yet mere passing the hat will not raise money sufficient for such luxuries. In order that the poor may benefit, these institutions should be well endowed at the start. A hospital for merely wealthy subjects would doubtless fail for reasons mentioned later.

In connection with group work, two or three quite different forms of activity have been foreshadowed. One is purely diagnostic in scope. A diagnostic hospital already exists in New York and a building will be erected at an early date to be known as the "Diagnostic Institute." The term "hospital" is really a misnomer, as no treatment will be undertaken. On the Pacific coast groups are active in work which is essentially diagnostic and which yet lays down the treatment indicated by the diagnosis. These clinics will be described in full later. A third form of activity is, primarily, treatment. At the Mayo institute, the Massachusetts General Hospital, and the Cook County Hospital of Chicago, we understand that group diagnosis in the California sense does not exist.

One internist makes a full examination and refers the patient to the proper clinic or clinics for treatment. The group men in California are satisfied that this is a grave error and refuse to apply the term "group medicine" to any of these famous centers of medical or surgical activity.

Who are the natural, the superior diagnosticians? The beginner who can spend many hours daily in some narrow field of activity may be the technical superior, especially if endowed with unusually keen senses or color perception. His responsibility is limited to seeing or hearing, and in hospital work his skill is often used by his seniors. With the final diagnosis or with treatments he will have no concern. It might be worth while for group ends to fit some of these men for group work. They will have no outside activities, and their compensation need not be high. In other words their status would be that of laboratory men. They might combine several diagnostic activities. Would not a good ophthalmoscopist make a good uroscopist as well? Men of this type could always be on hand, and the labors of the diagnostic staff would be curtailed.

How Diagnostician Acquires Skill

An ophthalmoscopist is a necessity to the neurologist, brain surgeon, syphilographer, and internist. Certainly in all obscure cases his services would be needed. As already stated or implied, a single individual might take up the entire subject of endoscopy, for the faculty of examining illuminated cavities with their color shades must be a general one of wide applicability.

Diagnosis, however, is much more than endoscopy, for we have heard gynecologists state that a year or year and a half must elapse before one can really understand the exact relations of the pelvic viscera; and about the same latent interval elapses in all special work before one really becomes confident of his diagnosis. As a rule, a man really learns diagnosis from prolonged and close association with an expert. Hence both self-teaching by personal experience and education through the experience of others should be utilized in group work. An unknown man who has been closely associated with an expert may be better for group work than the expert himself.

It happens automatically, however, that the man who is to treat the case is the one to have the last word in diagnosis because his treatment, whether for a single consultation or more, must be based on a diagnosis in which he concurs. Hence the make-up of the group may vary much with its aim, whether for diagnosis or full treatment. In the former case, much work could be given to

diagnostic technicians, but in a therapeutic group the same man must combine diagnostic with manipulatory skill. A diagnostic cystoscopist would have to be an accomplished operating cystoscopist as well. Apparently the same x-ray man would be used for diagnosis and treatment. The subject of electrocardiograph would belong under laboratory activities, as would perhaps the measurements of blood pressure.

A full diagnostic-therapeutic group is not altogether easy to visualize because of possible opposition in many quarters. Should it revolutionize medical practice, should all practitioners engage in group activities, all might be well in the end. Otherwise group medicine might antagonize family practitioners, specialists, and hospitals to a greater or less extent. According to the California idea, group medicine exists only through the good will of the family physician who regards it as identical with a consultation with a single consultant. The consultants and specialists in general are not strikingly antagonized as long as group medicine is for the benefit of the small-salaried man. Do not consultants and specialists admit among themselves that they could not thrive were it not for the patronage of the well-to-do?

We note under the head of surgery two opposing tendencies. On the one hand, there is a tendency for certain men to achieve prominence in certain fields, some quite narrow; one man does most of the brain surgery in a community while another has an imposing series of cases of operations on cancer of the rectum; a few men only do thoracic surgery with pressure-difference apparatus. The other or opposed tendency is for many men to enter a field as soon as it has been shown to possess possibilities. No technical difficulties appall them.

Difficulties of Group Diagnosis

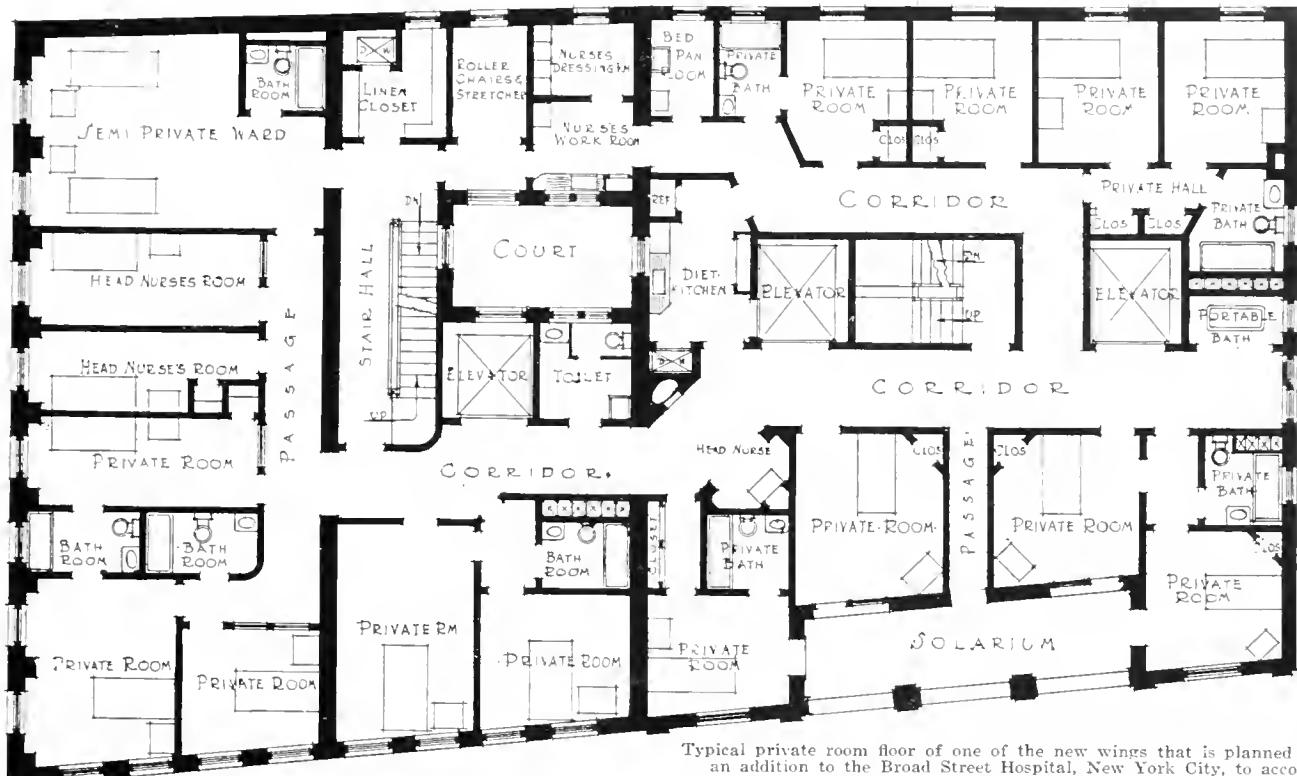

How will these tendencies affect group practice? A man with great prestige would not be likely to pool his issues with a group of less known men. On the other hand, a group would need the services of an expert in no wise inferior to the man of prestige. This could not always be obtained at once. The operating bronchoscopists frankly admit without the least jealousy that one of their number is technically their superior. They are rather proud of him and shine from his reflected light.

It will be remembered that one operator obtained a good start on the electrical destruction of bladder growths; after he had abundantly shown the practicability and utility of the method, a score of colleagues overcame the technical difficul-

ties, and now no urologist would refuse to master the procedures involved. Group medicine would encourage emulation because each group must have a man as good or nearly as good as the best outside talent. The success of the younger special surgeons in the Mayo Clinic has been due to hard work, study, abundant opportunities, and the stimulus of the ambition to compete with the best

yet hardly goes so far, because the latter is usually called in late while in a group diagnosis the aim is to have an early diagnosis.

Another question is now raised. Can an ordinary metropolitan hospital intended for emergency and routine work become an institute for group medical practice and still retain its original scope of activity? This question should be an-

Typical private room floor of one of the new wings that is planned as an addition to the Broad Street Hospital, New York City, to accommodate the broadened activities which are made possible by the co-operative, inter-departmental system of group treatment. (William Neal Smith, architect.)

independent men. Group medicine can pattern after them. If men are not available, they must be created; in the case of endowments money could be appropriated for training men in various ways. They could sojourn at special educational centers; at the Mayo institution, for instance, at the urological clinic at Baltimore, or, in fact, wherever the highest technical training is obtainable, anywhere in the world. At a urological institute in Madrid, students study cystoscopy on the cadaver and healthy living subject and use a variety of instruments, in addition to abundant clinical material. The many ways for obtaining special training are too well known to require details. A year or two as assistant to an expert is perhaps the best single way.

Many phases of practice would be in no wise disturbed by the advent of group medicine in a community as long as the latter had limitations of marked character. This is especially true if functions are diagnostic. It then simply replaces the old consultant in a certain number of cases,

swered at once in the affirmative. In any general hospital there are presumably accident and emergency wards, and the operation of the latter need not in any way prejudice the other work of the hospital. Accident cases are the very ones to benefit by group practice, as in the instance of fracture of the skull where the surgeon, neurologist, and ophthalmoscopist are all simultaneously in demand. It is the man generally smashed up with all functions disturbed who can profit most from the services of a group of specialists. In a large city a hospital of this type could readily take on a certain ambulance territory, and the service rendered should be superior in character.

Another question refers to the policy of an outpatient department in a group hospital. The essentials of dispensary practice have already been outlined. It is evident that a number of reasons could be adduced against associating dispensary with group practice. The first is that it would be essentially slipshod and devoid of real cooperation. If used at all, it would have to be conducted

on lines in harmony with the hospital proper. Three-fourths of the patients would represent cases requiring no deliberate group activities. On the other hand, cases in which the latter were really in demand could perhaps be given the benefit of teamwork. That there should be an outpatient or ambulatory service of some sort is conceivable, especially if there are no other dispensary facilities in the district.

In group medicine the medical specialists would to a certain extent be handicapped along lines of treatment, since they have no equivalent to the decisive surgical operation. This is offset in part by the fact that the medical disease is self-limited in many cases, and to discharge a typhoid case in first-class shape may be a feat comparable to a successful operation with good convalescence. Of diseases not self-limited, medical treatment will put patients on their feet in many cases with relative recovery. The percentage of these cases, however, cannot begin to compare with the surgical recoveries. In our opinion this is due to the wrong conception of the duties and scope of physicians as opposed to surgeons. It is commonly said by those who begin medical practice that nine out of ten who flock to them are not really ill, i. e., have no demonstrable organic disease. But if the practitioner had made himself familiar with the mechanism of the soul, as the surgeon is with that of the body, he would never pronounce these nine patients technically sound. In other words, the great majority of patients in this class demand a psychotherapist. While physicians who have never received this training or who object to it for one motive or another, cannot be made to take it up (although all successful men practice it unconsciously), this omission should be remedied by having in any medical group a neurologist who is thoroughly versed in medico-psychology. If we suppose that ordinarily the internist looks over the patient first and perhaps directs the entire examination — since someone must exercise this prerogative—a little reflection will teach us that the psychologist should be entrusted with the initial examination. He should be able to detect under any disguise the neurasthenic, hysterical, "hypo," and simulator in general. He would be apt to estimate the personality of the man correctly and likewise any defect of intelligence. He would also know how to rate the man's testimony. This, however, is doubtless open to practical objections. In most cases a complete examination along such lines would be out of the question, but the psychologist should certainly be present during the examination and on subsequent occasions and give the patient a mental rating. This form of testing has nothing

in common with an ordinary neurological examination, which might or might not be carried out by the psychologist. If the same man exercised both functions, he could obtain an idea of the mental state while conducting the neurological examination. The presence of a neuropsychologist is also of value in many other ways in group practice, as in dream and delirium analysis. It is conceivable that, in a group hospital, neurological cases would not be desired on account of their chronicity, but there could be abundant work for a man of this specialty as already indicated. In any case the group hospital of a large city would not care to trespass on the domain of highly specialized hospitals such as those devoted to the eye, nervous system, orthopedics, etc.

Place for Specialism in the Group

It would perhaps come about that group surgery would subdivide in time into brain and cord surgery, chest surgery, etc. One of the most valued members of a group is the anesthetist who has long been a special technician. In this connection, the term "technician" might come in time to remove some of the old odium attached to the words "specialist" and "specialism" which originally almost connoted quackery. The modern anesthetist must understand all forms of analgesia and narcosis. Alongside the anesthetist should be placed the man responsible for the cleanliness of the surgical outfit, and the two could be combined.

The question will sooner or later crop out: "May not the same man cover different group activities in his own person?" This question is a most vital one. Not a few men are equally qualified in several quite different technics. This polyvalence should be utilized at the start in the formation of the group. Men could be chosen who are known to be proficient in several fields. There is certainly a precedent in this course in the average laboratory man who often does the work of half a dozen technicians. Under so elastic a term as "pathologist," one man may be the chief autopsy functionary, curator of the museum, microscopist, bacteriologist, hematologist, general chemical analyst, experimental pathologist, maker of serums, and so on through a dozen more activities. Yet at the other extreme, in some hospitals, there is one man delegated for the Wassermanns alone. Much depends, of course, on the outside activities, as the true laboratory man is engaged in no other kind of activity; in other cases one of a group who has little time to spare is entrusted with a narrow line of work. In group activities this is likely to be the case, and it will not be possible to standardize the time of the different men.

This leads to the entire subject of cooperation and compensation of the group practitioners. Should a man devote whole or part time to his group work? In the Mayo institution, so far as we know, no man has any outside activities. We do not know how the men are compensated, whether by salary or percentage, but presume the methods of financial houses are followed. Much has been written about various aspects of this institution, but naturally the bookkeeping system is not discussed. If salaries are paid they would certainly be much smaller than the incomes of eminent independent specialists because the men at the Mayo institution are at no expense for upkeep of office and armamentarium. A general library makes it unnecessary to buy books and periodicals. This community is one of the attractions of group medicine, or might be made such. In a group hospital conducted on a democratic plan in a large city, it is hardly conceivable that men who combine to form the federation could give their entire time to group work. As a rule they would be men with good practices with offices centrally situated and probably remote from the hospital. If his headquarters were to be at the hospital, each man would require a certain amount of private floor space, and the various major surgeons would not care to use a common installation; they could not, in fact, because they might have the same hours. There would have to be arrangements for privacy equal to those in a physicians' building. A question to come up would deal with the privilege of doing other than group practice.

How Will Public View the Group?

This opens up a new and large problem. All cases are certainly not group cases, and it might represent an economic waste to treat them as such. Perhaps almost any patient could benefit in some manner from group diagnosis and treatment, but the idea of the group is based on the conditions arising from the combination of complicated disease in men of moderate circumstance. The very wealthy man is not likely to seek group treatment to save money. The element of time-saving might or might not appeal to him. One of the most cherished privileges of one type of patient is to wander from one physician to another. Moreover, the group ideas may suggest too strongly the "consultation of specialists" of newspaper mention, which usually means that the patient is almost hopelessly ill. In fact, group medicine being in the experimental stage, no one knows just how the public will react to it. No one goes to the Mayos' institution primarily for group treatment. People know of the Mayo broth-

ers but not much of the men who may actually operate on them. The name Mayo acts as a guarantee.

A group of medical men combining without the magic of a name could not expect this attitude from the public. The makeup of the group would perhaps convey little, and the requirements of ethics might suppress the names of the members on all stationery. Patients would come for treatment in several ways. First, the reputation of the hospital would gradually become known as embodying the new idea of group treatment. Second, the members of the group as private practitioners would send some of their clients to the hospital. Third, the general practitioner who has no hospital affiliations of his own would sooner or later act as a feeder to the group hospital just as in the past he has always kept ordinary hospitals supplied. It would be necessary to show him that the service is what it claims to be, for many practitioners have become embittered by various hospital abuses. The old-line hospital is still regarded as the last resort and the least of two evils, and all the odium which attaches to institutional care is shared in full by hospitals. A group institution would have a splendid opportunity to aid in dispelling this attitude.

Group Methods and Life Insurance

Group medicine works hand in hand with life extension examinations and insurance work in general. If a company of specialists have in the course of a diagnostic examination found a man comparatively intact with the exception of some condition which has been rectified after having caused temporary disability, would not their report increase the value of the man as a risk? Especially in the case of a man seeking large insurance? In cases of applications for \$100,000 or other large policies, the companies would perhaps send the man for a group diagnosis. It must not be forgotten that there is a good independent field for group diagnosis alone, as shown by the California hospitals and the recent establishment of a purely diagnostic institute in New York. Many individuals of their own accord would perhaps seek to know their actual physical condition in this manner. Group diagnosis would appeal strongly to the eugenists as superior to single examinations of a routine character, and prenuptial examinations would have an especial value that can be readily appreciated.

Does group medicine take cognizance of the possible examination alone or with treatment of a group of patients? We know that if two members of a family consult a physician together he is not likely to ask a double fee. Could group med-

cine guarantee any economic saving in examining husband and wife or two business partners? At first sight this seems doubtful. Insurance companies have never made reductions of this kind. It seems that the saving of time and effort would at best be very small and any reduction of fee would be purely a matter of good will. The condition would be different from cases in private practice in which two members of a family appear with syphilis.

New Status of the Hospital

We have referred to the classes of patients who are or are not suitable for group treatment and to the kinds of patients who might or might not present themselves for treatment. Should the hospital use strict selection in this matter in advance? To do so would defeat in advance the natural selection by the public and general practitioner. Yet in its literature to show the need for its existence the hospital should make public without any reference to cases not desired some idea of those whom it expects to treat. Much depends on whether in addition to taking on the special status the old status is also maintained. As this subject has been partly covered in earlier paragraphs, it is only necessary to state that a patient of the ordinary hospital type may receive group benefits when necessary or on general principles, while all patients who come solely for group advantages could be regarded as analogous to those coming for consultations in private practice and be charged on that basis. This leads to the question of consultation work. Can a practitioner bring a patient for group diagnosis just as he calls in a private consultant? This course would antagonize the private laboratories, for by going to the group hospital the physician obtains examinations of blood, urine, sputum, x-rays, etc., in addition to physical diagnosis. Or again, can a practitioner secure from the group hospital a "treatment" consultation as he does in ordinary consultation practice? In other words, after a group diagnosis, does the hospital lay out a course of treatment to be carried out by the practitioner in the patient's own home? Should the practitioner bring the patient at intervals for renewed consultation? It is evident that patients who could thus benefit would have to be men of some means. Group work would be cheap only comparatively speaking in what it would save in the long run. Even a single consultant may charge up to and at times over \$25.00. Most of these questions are answered in the California plan.

Touching on the question of origin of group medicine, we have already mentioned the leading role which was played by the development of spe-

cialties, although the presence of other factors was necessary to bring it to a head. We may, if we like, regard group medicine as a step in the natural evolution of combination or cooperation in medicine. This, of course, goes back to very old beginnings. All medical colleges, societies, journals, etc., represent cooperation on the part of some of the profession. The evolution of hospitals and dispensaries marks a most important step in this direction, and the striking fact that all but two per cent of the sick of the state are treated by medical men without any element of organization shows that this movement is still in its infancy. The establishment of public laboratories and the close cooperation between laboratory men and practitioners represent a marked step forward. The recognition by the general practitioners of specialists approved by them and the comity between the two belongs in the same category; the specialist can be likened to the reserve of an army to be called upon when its services are really needed. The general practitioner, however, does not cooperate with the specialist who builds up his own following and seldom consults with him. We refer, of course, to the country at large and not to the few metropolitan districts. Medical journal and book clubs and libraries are other examples of cooperation. It is, of course, easy to believe that group practice means another step along the same lines.

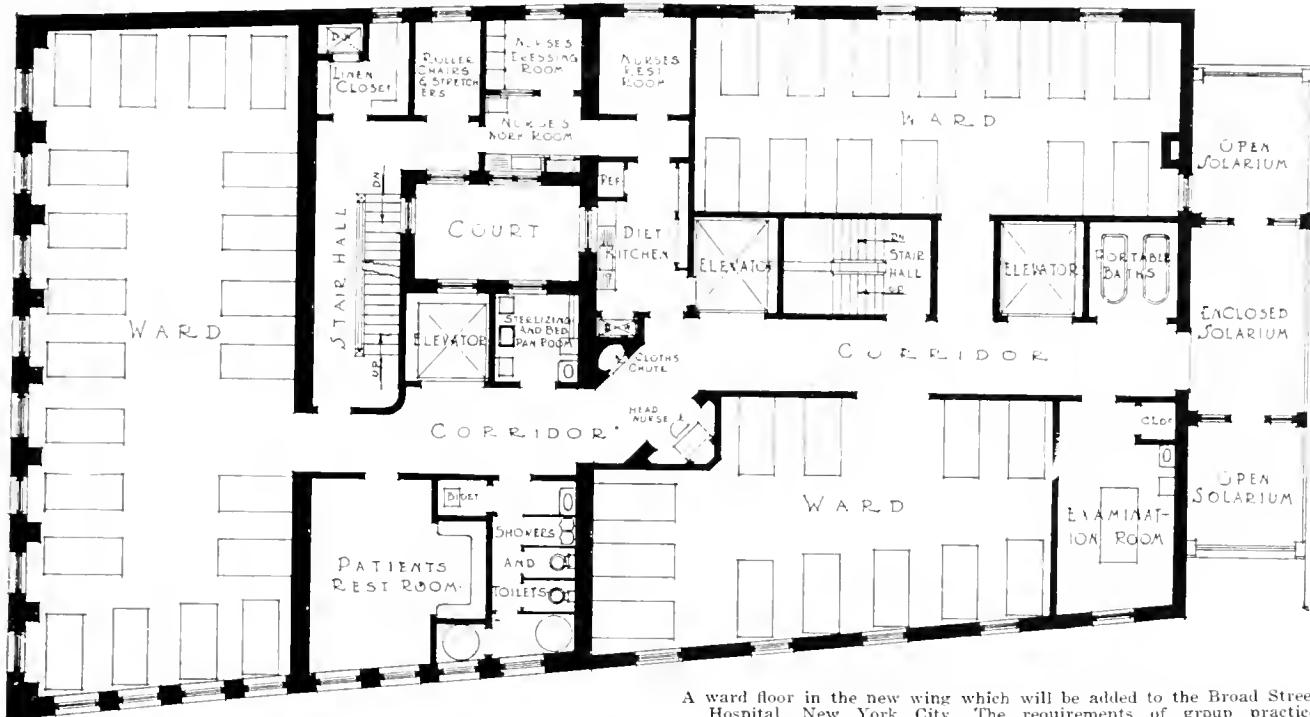

Group Is Safeguard Against Blunders

There is, however, much reason for upholding quite another view of the origin of group medicine. Data have quietly accumulated to show that blunders in the diagnosis made even in the best hospitals by the most expert clinicians are fearfully numerous. The Massachusetts General Hospital seems to have been the first to publish facts to support this view on a large scale, and with this announcement it is said that steps were taken to guard against such contingencies and reduce them to a minimum. But according to certain advocates of pure group medicine to be mentioned later, neither the hospital in question nor the Mayo Clinic has ever practised true group diagnosis. The patient is not examined by a group but by a single clinician, and then referred to the department or departments to which apparently he belongs. The claim is made that no one man has the skill to examine a subject for reference of this kind; that such a method is in no sense group practice; and that it is far inferior to group diagnosis as practised in some of the California cities.

So far as we know, group diagnosis, associated to some extent with treatment, began in San

Francisco in 1915 with the formation of the St. Luke's Hospital Clinical Club associated with the hospital of that name. Other San Francisco hospitals have followed suit, while in San Diego the Scripps Clinic was organized in 1917. The leading motive, according to a local writer, was the exposure of the frequent incorrectness or inaccuracy of hospital diagnoses as shown by autopsies

come. If this was \$100 monthly, the fee was \$35.00. The patient paid often no more than a single x-ray fee would have cost in a detached laboratory. In regard to the character of the cases treated, obscure ones only were received, the selection being fixed by the family practitioners who brought the cases. These practitioners often brought the same patients back for a further con-

A ward floor in the new wing which will be added to the Broad Street Hospital, New York City. The requirements of group practice have been kept in mind in designing the new wing. (William Neal Smith, Architect.)

carried out on a large scale in the Massachusetts General Hospital and other large clinics. Stated in a nutshell, "group medicine is largely a result of erroneous diagnoses in hospitals which could have been avoided by group study." As thus conceived, it was not the province of a group unit to take a patient away from his doctor or to treat him except as in any consultation when the consultant recommends the treatment indicated by the diagnosis. The patient's physician becomes automatically a member of the group, at least an honorary member for the occasion. The total number of hospital physicians in the group was fixed at twelve, and the average number to participate in a group diagnosis was seven. The patient was examined by the diagnosticians in succession and the reports made out in writing were reviewed at a joint session where the diagnosis was reached. In some cases the diagnosis was not made until after a second examination. The patient remained in the hospital on an average a little over four days, and the number of diagnostic hours averaged eighteen. The fee for the entire service was based wholly on the patient's in-

sultation, and, in general, every attempt was made to follow up the outcome.

The doctors were compensated as follows: they were assumed to play the role of ordinary hospital physicians who give their hospital time in return for experience and prestige, but in addition they received a stipend which was based on time spent in diagnosis. Further details are not mentioned. Evidently after the diagnosis was established, many of the patients entered the hospital for surgical or other treatment and paid the regular hospital fees.

Group Has Many Surgical Cases

During the first year at St. Luke's, the number of private patients examined was 265, and of this number 100 had major surgical conditions, 24 of which were treated by operation.

At the Scripps Clinic at San Diego, an independent foundation not connected with a hospital, the same course is pursued throughout. This is the first case in which private benevolence has founded a group diagnosis clinic for men of moderate means.

In conclusion, it is readily seen that group medicine is a complex entity which cannot be quickly or sharply visualized. There are many factors to be considered. First, there is the public. Who are to benefit chiefly by it, the rich, the well-to-do, small-salaried men, or the poor? As far as we have gone, the small-salaried man seems to be the chief beneficiary, the man who earns \$100 a month in a medium sized city;—this figure would probably not suffice for New York. The question should be suggested: "How can group medicine be adjusted to the needs of the rich on one hand and the poor on the other?" The rich man's family physician can easily summon a consultation of specialists but he does not take this step at the start. As stated elsewhere, the suggestiveness of the latter course of procedure is not pleasant, for it seems to connote a bad state of affairs. There are doubtless cases, however, in which the obscurity of the diagnosis would make such a course acceptable, and it is the obscure and exceptional case that is adapted for teamwork. In regard to the poor man, the out-patient department and wards of the city hospitals must supply him with group advantages, and, if his case is of enough scientific interest, he will probably receive the benefit of cooperation, but not to a much greater extent than hitherto. We have already alluded to the possibility of a group of men handling a group of patients on a sort of club or lodge plan, but the possibility of such an evolution seems remote. A few individuals with obscure ailments might combine to secure group diagnosis and obtain such reduced rates as a certain amount of economy of time and effort might warrant.

The Men Who Form the Group

Next to the patients, let us consider the makeup of the medical group. These might be men of prestige or simply men who are competent for the work. They will be full-fledged specialists or mere technicians. In the latter case there would be men who represent laboratory extension only,—men who use the endoscopic instruments and report the results of ophthalmoscopy, uroscopy, etc., but do not further take part in diagnosis. Such a plan might dispense with the group of ophthalmologists and otologists. The group members could be a democratic, self-determining aggregation, or else a few prominent men could create a body of diagnosticians out of young and little-known subordinates. They physicians and surgeons of a hospital could combine and use the

hospital facilities, or a group without hospital affiliations could combine and extemporize premises or else interest some men of the Scripps type to endow an institute. The material treated could be purely surgical, purely medical, or combined. The work could be diagnostic or consultation only in type, or diagnostic and therapeutic. The physicians could serve for experience and prestige only or for nominal compensation or could use a certain amount of commercialism, by catering to the well-to-do and charging large fees for operations, etc., afterwards sharing profits or paying the group members fixed salaries. Hospitals could be devoted to group work or combine the latter with ordinary hospital activities.

That a group of private practitioners without headquarters could carry out practice on the tandem plan seems not only wrong in conception but quite impracticable of execution.

INDUSTRIAL SURGEONS AT ATLANTIC CITY A. M. A. MEETING

Industrial medicine and surgery, their scope, and some future aspects of these branches of medical science, will be discussed by physicians and surgeons from industrial organizations and government departments, at the Atlantic City meeting of the American Medical Association, Wednesday, June 11, and Friday, June 13, in connection with the program of the Miscellaneous Topics Section.

The opening general meeting of the Association will be held in the Music Hall, Steel Pier, Tuesday evening, June 10, at 8:30 o'clock. The foreign guests of the Association will be introduced at this meeting, and the President's Address will be given at this time.

Following is a list of the speakers in the Miscellaneous Topics Section and the papers they will present:

WEDNESDAY, JUNE 11, 1919

SYMPOSIUM: SCOPE OF INDUSTRIAL MEDICINE AND SURGERY.

"Preventive Surgery as Demonstrated by Industrial Practice"; Irving Clarke, M.D., Worcester, Mass.; Discussion by Drs. Sherman, C. G. Darnum, or Corwin.

"Industrial Medical Practice and Sickness Prevention as a Factor in Public Health"; C. E. Ford, M.D., New York City; Discussion by William Alfred Sawyer, M.D., Philadelphia, Pa.

"A State Department of Health Collaborating with Industrial Medicine"; Edward Martin, M.D., State Commissioner of Health of Pennsylvania.

"The Enlarged Program of the United States Public Health Service, Division of Industrial Hygiene and Medicine"; C. W. Schereschewsky, M.D., United States Public Health Service, Washington, D. C.

"International Aspects of Public Health as Related to Industrial Hygiene"; Major George A. Soper, S.C., U.S.A.

General discussion of the symposium: Opened by Francis D. Patterson, M.D., chief, Division of Hygiene and Engineering, Department of Labor and Industry, State of Pennsylvania.

FRIDAY, JUNE 13, 1919

SYMPOSIUM: FUTURE ASPECTS OF INDUSTRIAL MEDICINE AND SURGERY.

"Lessons from Rehabilitating the Disabled Soldiers Applicable to the Industrial Disabled"; Col. Frank Billings, M.C., U.S.A. Discussion opened by James Bordley, Jr., M.D., Baltimore, Md.

"Value of Health Service to Business"; Arthur Young, special assistant to the president of the International Harvester Company, Chicago, Ill.

"Modernizing Our Medical Colleges by Adding Departments of Industrial Medicine and Public Health"; Otto P. Geier, M.D., Cincinnati, O. Discussion opened by David Edsall, M.D., professor of medicine, Harvard University, Boston, Mass.

"A Medical Service for the Small Industrial Unit"; C. D. Selby, M.D., consulting hygienist, United States Public Health Service, Toledo, O.

"Industrial Medicine from the Working Man's Viewpoint"; Whiting Williams, Cleveland, O.

"Industrial Rehabilitation of Belgium"; Dr. René Sand, of Belgium.

General discussion of the symposium by Victor Vaughn, M.D., Ann Arbor, Mich.

¹ Dr. James F. Mumford, late professor of surgery of Harvard University, was a pioneer in group medicine, although his efforts, which go back to 1910 or earlier, were not crowned with success. He finally combined group practice with sanatorium activities, in which he was engaged at the time of his death.

SYLLABUS OF ACTIVITIES FOR THE PROTECTION AND PROMOTION OF THE NATION'S HEALTH

BY S. S. GOLDWATER, M.D., DIRECTOR, MOUNT SINAI HOSPITAL; FORMER CONSULTANT ON HEALTH AND HOSPITALS TO THE BOARD OF ESTIMATE AND APPORTIONMENT OF THE CITY OF NEW YORK

I. Introductory

IN modern industry, in urban development, in the school environment of the child, in man's physical constitution, in nature itself, there exist many powerful forces that tend to undermine health. How greatly these forces are dreaded may be inferred from the efforts of the people, organized and unorganized, to protect themselves from disease and to escape the inevitable consequences of physical deterioration. These efforts cover a wide range of activity—from scientific research to the making of laws, from the co-ordinated activities of great and powerful departments of government to the breathing exercises of puny individuals, from the safeguarding of helpless infancy to the amelioration of old age, from the sweeping of streets to the cleansing of teeth, from the construction of model tenements to the destruction of unsanitary hovels, from the use of force to the appeal to reason.

As one interested in the public health movement, the writer has attempted to avoid mental confusion by classifying the subject matter which concerns the sanitarian and the hygienist. For working purposes, the syllabus which is here presented has been found convenient and useful. While it is fairly comprehensive in outline, much detail has been intentionally, and some, no doubt, unintentionally, omitted. Although what is given will perhaps not exactly fit the need of any other person, it is presented in the hope that it may assist beginners in their preliminary survey of the field.

The scientific foundation of modern hygiene is broad, but not broad enough to confer undisputed authority upon the public health expert who would like to define and to establish, for the mass of the population, minimum standards of living necessary to the attainment of maximum vigor of body and mind. Hence the public health movement requires encouragement and strengthening

The publication in MODERN MEDICINE of the accompanying syllabus of activities for the protection and promotion of Health in the United States is especially appropriate because it covers, or at any rate is intended to cover, the field which the new magazine has marked out for its own—industrial medicine and the nation's health.

As one interested in the public health movement, the writer has attempted to avoid mental confusion by classifying the subject matter which concerns the sanitarian and the hygienist.

The syllabus presented herewith suggests the need of unified effort throughout the broad domain of public health endeavor.

in the department of scientific research.

Where there is so much to be done, some things are likely to be forgotten. The function of the various specialistic societies in the public health field is to see that this or that important health need is made manifest to the man in the street, and duly attended to by the powers that be. This is a function that might be assigned to a Federal health department poss-

sessing broader supervisory powers than those of the existing organization of the United States Public Health Service.

It is the absence of a well-developed national health service that opens the door of opportunity and of duty to a multitude of private agencies, which may, perhaps, yet find some means of joining hands in a unified effort to reach their common goal. Already they have found a common meeting ground in the American Public Health Association.

The American Public Health Association in the past has undertaken and successfully completed many valuable studies. Why cannot that association, representing as it does all that is being done and planned in public health work, now embark upon the larger task of producing, in a series of volumes planned by a representative editorial board, a condensed encyclopedic presentation of the whole subject matter of practical sanitation and hygiene? It is a heavy task, to be sure, but one not beyond the combined power of the association's large and varied membership. Think of the impetus that such a production would give to public health administration!

The publication of the accompanying syllabus in MODERN MEDICINE is especially appropriate because it covers, or at any rate is intended to cover, the field which the new journal has marked out for its own—industrial medicine and the nation's health.

H. Syllabus**Eugenics**

- The study of heredity
- The application of the laws of heredity
- Segregation of the unfit
- Sterilization by law

Voluntary Birth Control

- Legal limits
- Activities and influence of physicians
- Attitude of social workers

Mothercraft

- Instruction of girls

Prenatal Care

- Under hospital auspices
- Directed from health centers
- Miscellaneous

Maternity Care

- Safeguards surrounding pregnancy
- Supervision of pregnancy
- Maternity insurance
- Suspension of arduous work
- Regulation of midwifery
- Training of medical students
- Home care
- Use of hospitals
- Hospital methods

Infant Hygiene

- Registration of births
- Routine treatment of eyes at birth
- Foundling asylums
- Boarding-out system
- Control of baby farms
- Encouragement of breast feeding
- Consultation centers
- Milk stations
- Municipal
- Private
- Restriction of employment of mothers
- Day nurseries
- Objects
- Number
- Regulation
- Summer outings for mothers and babies

Child Hygiene

- Preschool period
- Inspection and regulation of children's institutions
- Group records at health centers
- Correction of physical defects
- School period
- School medical inspection
- Periodic examinations
- Early treatment of defects
- Vision
- Hearing
- Nose and throat
- Teeth
- Skin
- Deformities
- Compulsory vaccination
- Prompt removal of infectious cases
- Tooth brush drill
- Mental examinations
- School lunches
- Publicly supported

- Privately supported
- Home visiting and instruction
- Public agents
- Representing school authorities
- Representing health officers
- Private agents
- Teaching of hygiene
- By special teachers
- By school doctors and nurses
- By ordinary school teachers
- Physical training
- Compulsory (state laws)
- Voluntary
- Athletics
- Gymnastics
- Breathing exercises
- School sanitation
- Ventilation
- Permanent systems
- Open windows between class hours
- Cleaning
- Fumigation
- Warning
- Lighting
- School baths
- Adjustable seats and desks
- Open-air classes
- Outdoor schools
- Vacation schools
- College organization
- Physical training
- Athletics
- Periodic physical examination

Child Labor

- Attempts at national legislation
- Attitude of Supreme Court
- State legislation
- Backward states
- Legal standards
- Approved standards
- Age limits
- Hours of employment
- Night work
- Employment certificates
- Revocation of certificates
- Supervision of employment
- Admissible and inadmissible occupations
- Children's Bureau
- Aims
- Organization
- Important investigations and findings
- Educational work

Employment of Women

- Extent
- Influence on health of employed women
- Influence on health of husbands
- Influence on health of children
- Regulation of hours, night work, etc.

Widows' Pensions

- Legislation
- Appropriations
- Health value to mothers
- Health value to children

Industrial Hygiene

- Periods of labor and rest
- One day's rest in seven
- The eight-hour movement

Industrial Hygiene (Continued)

- Summer vacations
- Sanitation of working places
 - Ventilation, temperature, and humidity
 - Lighting
 - Dressing rooms, lockers, bath and wash rooms
 - Pure drinking water
- Health measures
 - Lunch rooms
 - Rest rooms
 - Suitable clothing
- Equipment for recreation
 - Roofs
 - Gymnasiums
 - Playgrounds
- Safety measures
 - Inspection to reduce accidents
 - Measures to prevent
 - Injury from accidents and explosions
 - Electrical injuries and shock
 - First aid
 - Workmen's compensation
 - Fire protection
 - Building regulations
 - Safety appliances
 - Inspection
 - Department equipment
 - Volunteer organizations
- Occupational hazards apart from accidents
 - Measures to prevent
 - Injury from dust, fumes and chemical poisons
 - Exposure to excessive light, heat, cold, dampness, compressed air, and sound
 - Cardiac overstrain
 - Fatigue
 - Neuroses
 - Eye strain
 - Affections of the ear
 - Affections of the skin
- Cancer and occupation (x-ray)
- Theories of legislation
 - Prohibition
 - Regulation
- Occupational infectious diseases
- Reporting of occupational diseases
- U. S. Department of Labor
 - Scope
 - Methods
 - Cooperation with Public Health Service in field studies
- States and local administration
 - Industrial commissions and labor boards
 - Function and methods
- Municipal bureaus
- Voluntary trade boards of sanitary control
- Regulation of home workshops
 - Extent of manufacturing in tenement houses
 - Permissible home employment
- Basement and cellar workshops
- Physical examinations
 - To safeguard health of person examined
 - Placement or safety examinations to forestall injury
 - Examinations to prevent disease in person examined
 - To safeguard health of others
- Occupational clinics
 - Present scope
 - Needs

Economics of Health

- Labor movement
 - The demand for a living wage
 - The sanitarian's definition of "living-wage" in terms of human health and well-being

Military Hygiene

- Program of army and navy
 - Examination and rejection of recruits
 - Treatment of remediable defects
 - Vaccination
 - Physical training
 - Rationing
 - Control of venereal diseases
 - Personal hygiene of the soldier
 - Sanitation in camp
 - Sanitation of zones surrounding camps
 - Sanitation of barracks
 - Trench sanitation

Periodic Physical Examination

- Theory
- Practice (apart from schools and colleges)
 - Organized
 - Life extension institutes
 - Life insurance policy holders
 - Health insurance policy holders
 - Industrial groups
 - Government employees
 - Military
 - Civil
 - Unorganized
 - Individual practice
 - Influence of health insurance movement
 - Special training of physicians
 - Development of standard forms and methods

Mouth Hygiene

- Periodic dental examination and treatment
- The tooth-brush
- Use of antiseptics
- Training and employment of "dental hygienists"

Regulation of the Bowels

- By diet
- By exercise
- By massage
- By medicines and enemata

Recreation (see Exercise)

- Organized
 - Outings
 - Games and sports
- Unorganized
 - Popular habits and tendencies

Exercise

- Outdoor
 - Walking
 - Gymnastics
 - Public gyms
 - Public instructors
 - Swimming
 - Public instructors
 - Athletics
- Indoor
 - Gymnastics
 - Setting-up exercises
 - Breathing exercises

Posture and Gait

- Prevention of spinal curvature
- Prevention of flat-foot

Dress

- Rational summer dress
- Rational winter dress

Dress (Continued)

- Choice of linen, cotton, or wool
- Avoidance of tight clothing
- Cleanliness
 - Public wash houses
- Shoes
 - Growing use of rational footwear

Health Resorts

- Public parks
- National parks
- National health resorts
- State health resorts
- Seashore reservations
- Public piers
- Preventoria
- Sanitariums
- Vacation homes

Old Age

- Study of geratology
- Teaching of geriatrics

Post-Mortem Examinations

- Aspetic performance of
- Value of findings to preventive medicine
- Modification of laws governing

Communicable Diseases in General

- National quarantine
 - Consular reports
 - Foreign stations
 - Home stations
- State and local administration
 - Notification
 - Local
 - Interstate
 - Isolation in the home
 - Periods of isolation
 - Placing
 - Visits to enforce quarantine
 - Procedure on discharge
 - Public health "nursing"
 - Hospitalization
 - Compulsory (forcible removal)
 - Voluntary
 - Estimated hospital requirements
 - Available hospital beds
 - National
 - Army
 - Navy
 - Public Health Service
 - State
 - County and municipal
 - Hospital beds in private and semi-public hospitals
 - Duration of detention
 - Diagnostic laboratories
 - State
 - Municipal
 - Private
 - Mailing of specimens
 - Carriers and "contacts"
 - The search for carriers
 - The control of carriers
 - Control of "contacts"
 - Segregation in hospitals
 - In special wards
 - In cubicles
 - "Barrier" system
 - Transportation
 - Special vehicles

Communicable diseases in animals (see "Domestic Animals")

- Anti-spitting laws
- Placards
- Enforcement
- The wearing of masks during epidemics
- Disinfection of person
- Fumigation of air

- Vessels
- Vehicles
- Rooms
- Sterilization of objects
 - Cargoes and ballast
 - Bedding
 - Clothing
 - Books, toys, and other articles

- Use of chemical disinfectants
- Cleansing of surfaces
- Production of immunity by inoculation

- Smallpox
- Diphtheria
- Typhoid
- Rabies
- Whooping cough
- Tetanus
- Pneumonia
- Other diseases

- Free distribution of vaccines and antitoxins
- Control of production, sale, and distribution of bacterial preparations

Standardization of bacterial preparations

Bodies dead of infectious diseases

- Disinfection
- Transportation
- Disposal

Tuberculosis

- Immigration restrictions
- Extent of actual enforcement
- Scope of organization
 - Sanatoria, hospitals, and day camps
 - Number of beds
 - Duration of treatment
 - After-care
 - Results
 - Special provisions in hospitals for insane and in penal and other institutions
- Dispensaries for diagnosis and treatment
 - Standardization
 - Follow-up work
 - Supply of nourishing food
- Tuberculosis classes
- Home supervision
- Protection of exposed children
- Model tenements
- Associations and committees
- Legislation
 - As to hospitals and sanatoria
 - As to dispensaries
 - As to registration
- Indirect benefits of tuberculous activities to non tuberculous

Leprosy

- Existing state and local leprosaria
- Individual segregation
- National program

Hookworm

- Campaign for eradication
- Organization and methods

Social Hygiene

- Sex education
- Ethical training and self-control
- Prophylaxis
- Regulation
 - Reporting
 - Examination
 - Segregation
- Diagnostic clinics
 - State, municipal and private
 - National subsidy

Activities of Public Health Service

- Regulations governing interstate travel of infected persons
- Free distribution of preparations of arsenic
- Federal appropriations for the encouragement of research
- Marriage restrictions

Mental Hygiene

- The mental hygiene movement
- Activities of private agencies
- State activities
- Program of the Public Health Service
 - Training of experts
 - Improvement of educational methods
 - Mental examinations to determine suitable employment
 - Investigations
 - Promotion of legislation to encourage early treatment

Preventive Surgery

- Removal of tonsils and adenoids
- Treatment of dental foci of infection
- Circumcision
- Malignant disease (early excision)

Asepsis

- Application of principles in
 - Surgical treatment
 - Medical treatment
 - Nursing procedures
 - Ordinary life

Antiseptics and Disinfection

- In medical and surgical practice
- In nursing
- In ordinary life (apart from known infectious disease)

Water

- Supply
 - Surveys by
 - National, state, and local authorities
 - University personnel
 - Private sanitarians
 - Municipal water works
 - Private companies

- Protection against contamination of drinking water
 - Protection of water sheds

- Inspection
 - Examination of supply

- Protection of wells
 - Chemical and bacteriological examinations

- Purification
 - By quiescence or prolonged storage
 - By natural filtration
 - By physical, electrical and chemical processes

- Inspection and covering of tanks

- Household filtration

- Household sterilization

- Control of supply furnished to interstate travelers

- Individual drinking cups

- Regulation of public baths and swimming pools

Shell fish

- Regulations to prevent pollution of oyster beds, etc.

Ice

- Avoidance of pollution of natural and artificial ice

Soil

- Protection against pollution (see sewage)

Sewage

- Water-carriage system

- Elimination of cess-pools and privies in towns and villages

- Installation of sanitary privies in rural communities

- Purification by

- Filtration

- Irrigation

- Chemical precipitation

- Electricity

- Bacterial methods

- Dilution

Air**Housing**

- Legal requirements as to

- Factory buildings and stores (see Industrial Hygiene)

- Tenements and dwellings

- Prevention of overcrowding

- Windows

- Airshafts

- Restricted use of cellars

- Hotels and lodging houses

- Hospitals

- Dispensaries

- Other institutions

- Places of assemblage

- Public vehicles

- Ventilation

- Cleaning

- Heating

- The fixing of air standards

- Air conditioning (regulation of temperature and humidity)

- Mechanical systems of ventilation

- Ventilation of sewers

- Hot water vs. steam heating

- Use of electric stoves and appliances in place of gas

- Ventilation of sleeping rooms and living rooms

- Outdoor sleeping

- City parks and piers (see Health Resorts)

- Country life movement

Lighting

- Legal regulation (see Industrial Hygiene)

- Improved voluntary practice in

- Industry

- Auditoriums

- Dwellings

House Construction and Furnishing

- Sanitary flooring and interior trim

- Rugs vs. carpets

- Sanitary wall covering

Insects

- Protection against insects as carriers

- Mosquitoes

- Drainage

- Use of oil

- Fish control

- Larvacides

- Screens

- Prophylactic use of quinine

Insects (Continued)

- Flies
 - Stable inspection
 - Garbage protection
 - Food covering
 - Larvacides
- Fleas
 - Pulicides
- Lice
 - De-lousing
- Bed bugs
 - Insecticides
 - Sterilization of bedding
- Ticks
- Rat extermination

Domestic Animals

- Tuberculin testing of cows (see Milk)
- Inspection and licensing of stables
- Notification of communicable diseases
- Exclusion of diseased animals from cities
- Destruction of diseased animals
- Removal of dead animals
- Dog muzzling

Food and Drugs

- Food contamination in general
- Supervision of
 - Slaughter houses
 - National, state and municipal inspection of animals and meat
 - Ante-mortem inspection
 - Post-mortem inspection
 - Factories
 - National, state and local supervision
 - Sanitary and other regulations
 - Bakeries
 - Markets
 - Bottling establishments
 - Restaurants
 - Soda fountains
 - Examination of food handlers
 - Sterilization of eating utensils
- Food adulteration in general
- Sale of deleterious food prohibited
- Food condemnation and destruction
- Food preservation
 - Cold storage
 - Time limits
 - Drying and canning
 - Salting, smoking and pickling
 - Chemical preservatives
- Choice of food
 - Balanced rations (elimination of dietary cause of certain diseases)
 - Overeating
 - Rationing as an emergency measure
- Sanitary significance of cookery
 - Uncooked food as a vehicle of disease
- Instruction in cookery
- Milk production and distribution
 - Farm inspection
 - Cattle testing
 - The Bang method
 - Examination (sampling)
 - Grading
 - Standards
 - Labeling
 - Limited use of lowest grade
 - Disposition of substandard and adulterated milk

Pasteurization

- Regulation and inspection of plants
- Refrigeration
 - Commercial
 - Domestic
- Milk products
 - Cream, skimmed milk, condensed and evaporated milk
- Sanitary bottling
- Medical milk commissions
- Misbranding and adulteration of foods and drugs
 - National pure food laws
 - Bureau of chemistry
 - State and local regulations

Prevention of Drug Addiction

- National, state and local legislation
- Habit-forming drugs in patent medicines
- Tobacco habit
 - Reference to in school hygiene courses
- Coffee habit
 - Caffeine-free coffee
 - Use of substitutes

Prohibition and Temperance Movement

- Notable alcohol investigations and their results
- Activities of American Medical Association
- Anti-saloon League
- Laws requiring school instruction in hygiene, with emphasis on evil effects of alcohol
- State prohibition and local option laws
- Extent of enforcement
- The recent federal constitutional amendment

Miscellaneous Sanitary and Safety Measures

- Plumbing regulations
- Comfort stations
- Sanitary soap containers
- Individual towels
- Laundry regulations
- Hotel regulations
- Lodging house regulation and inspection
- Regulation of barber shops
- Regulation of boarding houses
- Regulation of sale of wood alcohol and other poisons
- Licensing of persons in various occupations in the interest of health and safety
 - Physicians
 - Nurses
 - Undertakers
 - Druggists
 - Plumbers
 - Elevator runners
 - Engineers and firemen
 - Peddlers
- Reporting of deaths and cause of death
- Burial regulations
- Cremation
- Collection and disposal of garbage
 - Cremation
 - Reduction
 - Dumping at sea
- Collection and disposal of ashes
 - Covered containers
 - Covered vehicles
- Disposal of refuse
- Treatment and disposal of industrial waste
- Street cleaning
 - Sprinkling and washing
 - Sweeping
- Labor camp sanitation

Nuisances

Citizens' complaints
 Authority of health officers
 Authority of police officers
 Regulation of offensive industries which produce
 Dust
 Smoke
 Odors
 Noxious fumes
 Anti-noise regulations

The National Congress

Attempts to create an adequate national department of health

The State Legislatures

Delegation of powers of regulation to health officers
 Progress in legislation affecting efficiency of state health departments

The Courts

Attitude toward sanitary measures
 The extent of the "police power" of health officers
 Enforcement of sanitary measures
 Recognition of legal responsibility of cities and of private citizens for the spread of infectious diseases

Health Departments

The U. S. Public Health service
 State and local departments
 Statutory powers
 Types of organization
 Methods of appointment

How applied

WHERE BOYS GROW STRONG

ONE phase of the health crusade for school children has been the establishment of nutrition clinics. How the nutrition clinic and outdoor life in camp were combined in a study of under-nutrition among New York

This is what a camera man saw when he peeped into a tent at dawn, at the Southfields (N. Y.) camp, just before reveille was sounded. The morning call was sounded daily at 7 o'clock, and things began to happen when this group of lusty health-builders were roused.

school children is shown through the camera's lens in the illustrations reproduced here.*

The New York Association for Improving the Conditions of the Poor, aided by the *New York Globe*, established this camp at Southfields, N. Y., in 1915. One hundred boys were selected for the studies in nutrition. They remained in the camp an average of twenty-four days. A carefully planned, balanced diet was provided.

All the youngsters received three substantial meals daily, and milk and whole-wheat crackers in the middle of the morning. Whole-wheat bread was used exclusively. No coffee was provided. The purpose sought in the experiment was to provide a diet not only adequate, but also well balanced.

The boys were weighed when they first came to camp and at intervals of from five to nine days thereafter. The average daily gain in weight was three and one-half times as much as the normal increase to be expected from boys

of this age. The hemoglobin showed an average gain of 6 per cent by the Sahli test and 4 per cent by the Tallquist. There was an average increase of 9 per cent in the red blood corpuscles for each child.

These boys from the schools of New York City were below the normal weight for youngsters of their age, and were under-nourished. They are learning the lessons of health in this outdoor school. They are finding out that good food, fresh air, exercise, and regular bathing can make a healthy, strong body out of an under-developed body.

Reveille was sounded at 7 o'clock, and the boys immediately raised the sides of their tents and set their cots and blankets out in the sun and air. Twenty minutes later came the signal for a setting-up drill of five minutes, followed by a dip in the lake or a washing up. At 7:45 mess-call summoned the boys to breakfast, after which they replaced their cots and tidied up their tents and the surrounding ground. Swimming and boating were in order when assembly-call sounded at 10 o'clock.

Most of the boys—80 or 90 per cent—could not swim on arrival at the camp. Practically all—over 95 per cent—could swim on their return to the city. Fishing, rowing, games, hiking, etc., followed the bathing period until 11:45, when milk and crackers were served. After the noon dinner, rest for one hour was compulsory.

At the end of the hour of rest, the boys were allowed to either join in some diversion planned ahead for the afternoon or to follow their own inclinations until the supper hour at 6 o'clock. Each evening at 7:15 a camp fire was lit. Around it stories were told and songs were sung. Taps sounded at 9 o'clock.

Exclusive of executive and administrative salaries, the total cost of the experiment was \$9,113. This makes an average of 84 cents a day for each boy.

A view of the woodland site at Southfields, N. Y., where a camp and nutrition clinic were conducted as an experiment in health building among school children from the City's crowded districts.

MEDICINE AND INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

THE NEED FOR LEADERSHIP IN MEDICINE

THE experience of the profession in the last four years in mobilizing the medical forces of the country for military purposes, as well as for the protection of the civilian population, has pointed out in no uncertain way the need for improvement in the technic of teaching medicine. Evidence is at hand from all quarters that while loyalty and devotion to the cause, and a desire to serve the sick and wounded, was universal in the profession, the average physician's attainment was a distinct disappointment to all teachers and leaders in the profession. Also be it noted that the lack of diagnostic and clinical capacity was almost as apparent in the graduates of the last ten years as in those men who graduated before the days when medical colleges had attained their present high standards.

Greater, however, than even the lack of his scientific attainment was the lack of administrative ability of the average physician. Suddenly called upon to establish large hospitals with all of the professional facilities, physical equipment, and executive ability needed to have them properly function, the army learned to its sorrow that the profession at large had no fitness for such service. The doctor was found to be an individualist to the extreme. He had never thought in terms of group action, whether for the purpose of preventing an epidemic, or attending to matters of sanitation on a large scale.

Perhaps one of the most valuable by-products of the war will be the realization that has come to the members of the profession that they are an integral part of the world movement; that until they qualify themselves in sufficient numbers to better understand the broad bases of community life in all its relations, the tremendous import of preventive medicine, the absolute necessity for better organization of the medical profession by groups, for diagnostic and curative purposes, the world at large will make relatively little progress.

Failure on the part of the leaders of the pro-

fession, and particularly the teachers in our colleges, to thoroughly understand the social and economic values that scientific medicine may add to the nation's wealth; failure to think out and prepare programs for the more complete application of preventive medicine; failure to make more generally available the best scientific medicine for the masses; has already forced into their field of action the social reformer with all sorts of patent legislation designed to meet the deficiencies of the profession's work. Intelligent, forceful leadership alone can save the profession and the public from such ill-considered legislation.

Attention is deserved, therefore, to such factors in the teaching of medicine which can in any way contribute to the solution of some of these very vexing problems. The profession at large will never understand the immensity of the problems it faces, nor the manner by which they may be met, unless many graduates of the near future will center their attention upon, and enter into the life of public health and preventive medicine.

In the same way, I believe it may be said, that by no other method may all of the benefits of modern medicine be brought so quickly to the assistance of the great mass of people, the workers of the country who are the backbone of the nation, as through the prompt training of a large group of industrial physicians and surgeons, later to be placed in executive positions in industry. There, in these large units of society they will function not only as plant health officers, in charge of sanitation and personal hygiene, but their clinics will act as clearing houses for the diagnosis of surgical and medical defects, either rendering the educational and curative measures or sending the patients to the properly qualified physicians and surgeons of the surrounding community. Thus they may serve the health departments directly in the control of morbidity, and by early diagnosis and prompt reference to consultants also affect the mortality curve.

EDITOR.

OPPORTUNITIES FOR INDUSTRIAL SURGEONS

BY R. M. LITTLE, DIRECTOR, SAFETY INSTITUTE OF AMERICA, NEW YORK CITY

THERE are increasing opportunities for industrial surgeons of the right sort. Which is the right sort? Not the old-time "company doctor;" not the general practitioner; not the exclusive specialist, and not the surgical aristocrat. The right sort of industrial surgeon is first of all a man who loves his fellow men and who is filled with the enthusiasm of his profession because of the good which he can do in the world. A real industrial surgeon is well educated, with hospital experience—who keeps up with the best medical and surgical knowledge and practices, is imbued with a spirit of constructive service, is interested in industrial life, and has some vision and imagination as to the importance of his work. No man is more important in a large industrial plant, or in the service of a group of small industries, than the industrial surgeon with these qualifications.

Dealing Successfully with Men

A few years ago a young man who had been graduated from a university and from one of our best medical schools, after serving four years in a hospital under one of the greatest surgeons in the country, elected to become the surgeon at a large industrial plant. His chief discouraged him because he thought his talents could be used to greater advantage in another line. But the young man had been associated with working men, had observed the way they were treated by company doctors and some private practitioners; he was interested in industries, and felt that he wanted to spend his life in the midst of our great industrial processes. When he reached his place of employment he found a little dispensary not larger than a box car, in the midst of the great works, unattractive and poorly equipped, and little appreciated by either the management or men. The opportunity was so unattractive that he did not unpack his trunk for two months. He paid a visit in the meanwhile to the city where he had received his medical education and hospital training and told his chief the situation. The great surgeon said to him, "Young man, if the

EXTENSION OF MEDICAL SERVICE

It is utterly impossible for the wage-earner to get the benefits of modern medicine and surgery if he must go from one practitioner to another for special treatment.

In an industry this service should be furnished by the management in a well-equipped clinic or hospital presided over by a broad-minded, skillful industrial surgeon; and in the community each citizen should be able to secure this treatment at a clinic or hospital where a group of specialists work together. The day has come for better organization of medical service both in industry and in the community.

workingmen and has become the chief surgeon of one of our greatest industrial corporations. He is an industrial surgeon of the right sort. He knows surgery. He keeps up to date. He knows men—workingmen—he is interested in them. He likes them; therefore, he understands them. He gives them the very best service of which he is capable—nothing is too good for them when they are hurt. He is interested in their homes and in the community where they live. His influence radiates throughout the whole organization. He cooperates intelligently with the employment, safety, and compensation divisions. He is alert to the general health conditions of the community. He is very much on the job and receives great returns in the good will and appreciation of thousands of men, in addition to a good salary. There are others like him.

The Wrong Type of Doctor

Then there are the "would be" industrial surgeons of a different sort; that kind which brought the name "company doctor" into disrepute; the medical man or surgeon who engages to do the work for a company, a lodge, or some fraternal organization at so much per case, performing his duties in a listless and perfunctory way, with his eye only upon the amount of money which he receives. This sort of an industrial surgeon or medical officer satisfies neither the company, fraternal organization, or working people, and should not be satisfied with himself. Fortunately, the growing intelligence of the country means diminishing opportunities for men of this type. May they rapidly disappear!

president of the company does not know that you are on the ground, it is up to you to go back and let him find it out!" Having the right mettle, he returned, unpacked his trunk, rolled up his sleeves and went to work. To-day he has one of the best built and equipped small hospitals to be found in the country, with a superb organization of assistants and nurses. He has gained the confidence and good will of thousands of

Three strong influences are making increased opportunities for good industrial surgeons.

First: The growing intelligence and deep concern of employers for the health and well-being of their employees is the first of these three influences. During the last decade there has been a remarkable change in this respect. Simple fundamental facts about life are coming home to the employing class. They are learning that the six prerequisites to a normal life are health, wealth, knowledge, friendship, esthetics, and righteousness. Those who study the industrial problem, now acute and full of commanding interest, recognize that it is a sound principle of industrial management to look after the health of the employees carefully. Good workmen are healthy workmen. Production and contentment rest upon health as the keystone of the arch. Work places must be safe and sanitary. Occupational diseases need to be prevented and injuries properly and fully treated. Forward-looking employers today are incorporating industrial surgery and its corollaries as a fundamental part of their organizations. It pays them in dollars and cents and brings other returns no less valuable. An industrial plant with five hundred employees may profitably employ an industrial surgeon for full time, particularly in hazardous industries. Not many have done this, but they will do it within a few years. An industrial surgeon is indispensable in a similar plant of one thousand employees. A large corporation with many plants has a dispensary or small hospital at each plant. There is a growing opportunity, therefore, in our larger industries for industrial surgeons who have an industrial point of view, who are well equipped professionally and who will put their hearts into the work in harmony with other branches of the management.

Compensation Laws Extend Practice

Second: Compensation laws make opportunities for industrial surgeons. Such laws now operate in thirty-nine states, three territories and in the Federal government. The proper administration of these laws places an emphasis upon skilled industrial surgery. The money paid to an injured workman is not as important as the medical service which is furnished him. Unfortunately, in many states the medical service is limited as to time and expense. The tendency, however, is to increase the time and enlarge the amount which can be paid. It is only a question of time until the compensation laws will be changed to provide all reasonable medical, hospital, and surgical attention to those who are injured in the course of their employment. This means that well qualified surgeons will have in-

creasing opportunities for their profession in this field. There has been considerable dissatisfaction in the profession because of the way in which the medical service has been controlled by commissions, insurance companies, and employers. There is some ground for the irritation, but a better day is coming. Physicians and surgeons must recognize that rates for industrial surgery when paid by companies per case, will be industrial rates, lower perhaps than obtain in private practice in well-to-do communities, and much less than popular specialists receive for their work. In the nature of the case it will be so. Naturally, many physicians and surgeons do not care to treat industrial patients. The average man, however, may well afford to do so, as he is sure of his pay, and the amount will not be so much less, than he would receive in general practice, and sometimes more.

Hospital Service in Industry

The intelligent workman dislikes nothing more than to be a charity patient. He should never be treated as such. It injures his self-respect. Whenever a physician treats an employee in his private office or in a hospital he ought to give the patient the best service of which he is capable. Some physicians and surgeons are but little less than criminal because of the perfunctory way they treat injured men, permitting infections, making wrong or imperfect diagnoses, and neglecting also to care properly for their patients. It is to be desired that industrial accidents shall be treated by those who are experienced in the work. A hospital which receives accident cases ought to be specially equipped for the work and have a staff interested in and skilled in caring for these cases.

In some of our large cities, physicians with an aptitude for this work have developed clinics and small hospitals and serve a number of industries. They are helping to develop the group system of medicine and surgery, a plan which is destined to grow and become highly serviceable and influential. In one of the small cities of the Middle West, where the general hospital facilities are not adequate, a surgeon with vision and practical business ability has developed a clinic and hospital with an experienced staff and does the work for several railroads and large manufacturing plants. He has a corps of skilled assistants. Every injured man who passes through his hospital receives the best medical and surgical attention. Many of his patients come to his hospital because of the poor work done by local practitioners. The companies send their injured men to his clinic and a compensation commission has effected a business arrangement with him to care for all

the employees of an important industry. The working people of that general community are helping to make his clinic popular, as they tell one another of the considerate and skilled service which they receive there.

There are many communities throughout our country where there are opportunities for surgeons with ability to develop a similar group system of treating industrial injuries and diseases. The physician needs to know how to deal with the management of industries and the compensation or accident boards and be competent also to develop and manage a skilled staff, all of whom will have the industrial and social point of view.

Third: The third influence which will help to make opportunities for industrial surgeons is the growing appreciation of the economic value of health. It is estimated that the working people of the country lose on an average nine days each year because of sickness. Much of this sickness could be prevented. Further, it is obviously true that a multitude of sick people continue at work when they ought to be under treatment at home or in a hospital. The loss to industry through sickness is much greater than on account of accidents. Indeed, the economic loss because of ill health is second only to the loss on account of labor turnover. The better organizing of industry which is now taking place will emphasize the health phase of industry as well as accident prevention and suitable conditions of labor. The industrial physician or surgeon, therefore, will have his place right by the side of the employment manager. All applicants for positions should be, and in time will be, given a careful medical examination, not to reject them or discriminate against them, but in order to classify them in the works. Of course, some will necessarily be rejected. Unless the physician or surgeon who makes these examinations has the industrial point of view and is in sympathy with working people they will resent the physical examination; but a physician or surgeon of the right type who understands workingmen, and who sympathizes with their point of view, can solve this phase of the problem.

Industry Leads in Teaching Health

Initial physical examinations at the time of employment are fundamental to the right placing of employees but should be followed by periodic medical and physical examinations of all employees. This should take place at least every six months and some employees ought to be examined more frequently. When this becomes the custom in most of our large industries and is accepted by citizens generally, a great step ahead will have been taken in protective health measures. The

worth of such a system can be demonstrated more easily in a large industry than it can be in the community at large. Perhaps, therefore, the better organized industries will become teachers of the community in this respect as they have in many others through accident prevention, recreation, insurance, playgrounds, etc. If half the thought and money should be employed in prevention of sickness, accidents, and labor turnover that is expended in payment for accidents, sickness, and labor turnover, our country could soon pay the gigantic war debt.

The war debt and increased taxation will compel a more scientific and careful organization of industry and mode of life for all citizens. In this respect, perhaps, it is a blessing. We are about to learn that we cannot afford accidents, sickness, and a labor turnover of 100 per cent or more in many of our industries. Capable industrial surgeons will find their place, and function effectively in the better economic and social organization which will shortly be ushered in.

Physicians Most Socially Minded Men

But let it be remarked that physicians and surgeons to succeed in this work need to have the social and industrial point of view. The one who has an individualistic attitude will not succeed. He will not get along well either with the workingmen or the management. Perhaps the majority of medical men are individualists; in one sense their profession makes them such. The general practitioner is apt to be an individualist. He treats individual patients at his office, in their homes and the community hospital. For the most part he is a single-handed workman. If he is a specialist he may be even more individualistic than the general practitioner. This is the reason why it is so difficult for medical associations to agree upon principles and methods for community health and social betterment. Yet the principles of biology and the facts as to bacteriology, of infections and contagions, all emphasize the social principles of life. Every well educated physician or surgeon knows that health depends upon many factors; likewise the proper treatment of sickness. All that physicians and surgeons need to do is to follow out the fundamental principles underlying their profession and the laws with which they cooperate to prevent sickness or to restore health and they will have the social point of view. Indeed, physicians should be among the most socially minded of men and furnish leaders and statesmen who will develop great methods of prevention suitable to an industry, the community, and the State. Of course, the community makes physicians and surgeons what they are in part, but the time has come for the profession to produce

some courageous pioneers who will put the emphasis upon prevention, broad health measures, physical examinations twice a year for all people, and group methods of treating sickness when it occurs. It is utterly impossible for the wage earner to get the benefits of modern medicine and surgery if he must go from one practitioner to another for special treatment. In an industry this service

should be furnished by the management in a well-equipped clinic or hospital presided over by a broad-minded, skillful industrial surgeon; and in the community he should be able to secure this treatment at a central clinic or hospital where a group of specialists work together. The day has come for a better organization of medical service both in industry and the community.

HEALTH SERVICE—HAMMERMILL PAPER COMPANY

BY M. HARRISON, MANAGER, EMPLOYMENT AND SERVICE DEPARTMENT, ERIE, PA.

HUMAN relations in industry is one of the great problems confronting American business to-day, and a subject that is receiving the earnest thought of the biggest men in the country.

Manufacturing concerns have given recognition to the importance of this question by the establishment of centralized departments to deal specifically with all phases of this subject, the executive heads of these departments being styled directors of personnel, supervisors of personnel, directors of industrial relations, superintendents of employment, employment managers, etc. Whatever the title of the executive, his position is a very responsible one and he ranks in authority with any other executive officer. He should report on the activities of his department only to the management direct.

At the Hammermill Paper Company a centralized department known as the employment and service department, has to do with all questions of industrial relations. In this brief article we have to deal with but one phase of this work, although the most important of all; that is, Health Service. This division is of primary interest, as the health of the worker and his family reflects directly upon production, quality of work, and earnings.

The drawing (Fig. 1) shows a lay-out of our department, linking together under one roof all the activities covered in our work.

Particular attention is called to the medical department, which embraces the doctor's examining room for medical examination prior to employment. After a man is interviewed and decided upon for a position, he passes across the corridor to a booth which is provided with a seat, hooks for clothing, and a mirror. He removes sufficient clothing to permit of physical examination. After the doctor's examination he goes back to the booth, dresses himself, and passes over to the

employment office for further instructions. The number of booths necessary depends upon the size of the plant and number of hirings. Three are sufficient for our needs.

It will be noted that we have a nurses' room and an office supply room for medical supplies.

The first aid room, when completed, will be equipped with all necessary appliances for the sterilization of instruments, dressings, gowns, and utensils. A corner of this room will be set aside for laboratory examinations such as urine, blood, and sputum analyses. This room will be used for both first aid and dispensary work. In cases of emergency when it may be necessary to handle male and female patients at the same time, provisions have been made to divide the room into two compartments, as will be noted in the drawing. Every modern and sanitary convenience will be provided for the convenience of the patient.

This department is not in operation yet, but the plan has been adopted and we hope to have it in working order before the end of 1919. At present our employment offices are all together, but our medical department is in another building.

Our health supervision may be classified in the following groups: Medical Examination; First Aid; Safety Service; Sanitation; Home Visiting of Absentees; Compensation; Education.

Before discussing the work of the various divisions of the health service, I want to make clear the underlying principles we keep before us in this whole matter of human relationship. If it is to be a success it must be done on a strictly business basis. It must pay in dollars and cents both to the concern and to the employee. It is not philanthropy, charity, or social uplift. Care must be exercised that it be not misunderstood by the worker as paternalism.

We do not use the word "welfare." This is a

much abused term and is looked on with suspicion by the employee. We believe "service" is a much better expression. What we are working for is the square deal, the best possible working conditions, the best wages we can pay, and the goal—ultimate contentment for all. This is our aim. This is what we are striving for, and this is the thought we try to get home to all of our workers.

Why should not the human element, the most precious raw material of all, receive the same attention that mechanical and plant equipment does? It is no more than common justice to the individual. He is entitled to work in good surroundings with plenty of fresh air and good light. He is entitled to protection against accidental injury, and to have his health cared for and to be protected from infectious, contagious, or communicable diseases that may be brought into the shop by the new comer.

In the final analysis, what we do in the way of health service is for the best interests of the company, as well as the employee. This is the only ground upon which this work should stand and the only basis which would justify its existence. The worker wants to retain his self-respect—in no other way will his full cooperation and good will be received.

Medical Examination

Directly linked up with high production, good morale, and a stabilized working force, is the health of each employee. When a man is in good health he is brimful of energy and radiates good cheer, which is infectious to other workers about him. The reaction is just the opposite if he is ill

or troubled with some chronic condition; he may not be ill enough to lay off, but just feels depressed and listless. As a consequence his production falls off, he does poor work, earns less money, and becomes dissatisfied. He is not affected alone, because the company and his fellow workers also share in the loss of efficiency. Through proper medical examination before employment a great deal of this can be prevented.

Examination of the mouth is a very important factor in this work. Badly decayed teeth, and especially poorly filled root canals with abscessed condition of the roots, are the direct cause of many chronic conditions.

Many men are employed who have old hernias which break down after they are on the job, for which the company has to assume responsibility in the majority of cases.

Defective eyesight, color blindness, incipient tuberculosis, venereal diseases, flatfoot, varicose veins, and defective hearing, are among the many other conditions brought to light after the man is on the job and we visit his home to find out why he is losing so much time. In many instances all of these conditions would be remedied by medical examination before employment.

Reduction of hours off has a very important bearing on the earnings of the worker and production of the plant. When a man loses time, he not only loses in wages but the company loses the services of a skilled operator. It costs money to break in a green man to do his work until the skilled man is able to be back on the job.

Then with reference to that very vital question of scientific selection of employees and fitting the man to the job, how are we going to know what

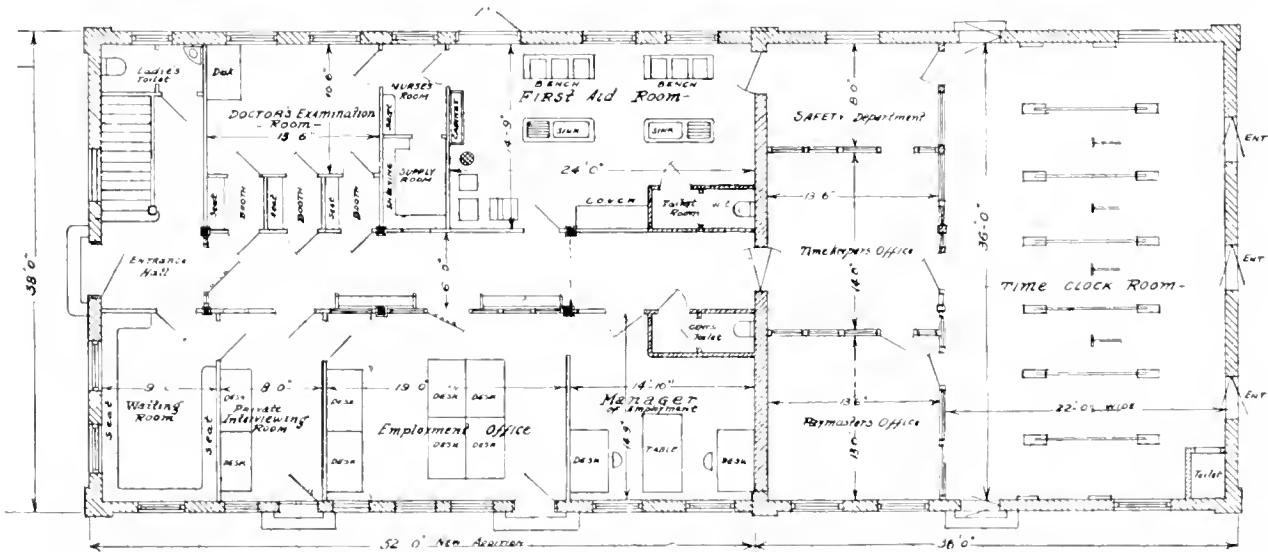

Fig. 1. The medical examination room and the employment office of the Hammermill Paper Company are directly across a corridor from each other. All of the activities of the health service for employees are linked together under this one roof. The medical examination service, the first aid service, the safety service, and the directors in charge of plant sanitation, home visiting of absentees, compensation, and education have centralized offices in this building.

kind of a job is best fitted for him if we do not know his physical condition, as well as his mental equipment? Furthermore, medical examination is the one and only means of protection against infectious, contagious, or communicable diseases being brought into the organization by the new comer.

From the foregoing it will be seen that the arguments in favor of medical examination are: (1) protection, (2) production, (3) cooperation.

First Aid

The first contact with the injured or sick employee is had through the first aid department. This department, in direct charge of a trained, first-aid nurse, under supervision of the plant physician, is equipped in every way to render quick and efficient service. All minor injuries and redressings are cared for here. More serious injuries are removed to the hospital. We do not maintain a plant hospital. Serious accidents are very few, due to eternal vigilance along safety lines. Very good hospital facilities are available in town. An ambulance can reach us in ten minutes. No discomfort is suffered by the patient, as first aid care is promptly given by the time an ambulance has arrived, so that there is no nerve-racking wait to be endured. Unless patients want their family doctor, our plant physician takes care of such injuries at the hospital. Our two local hospitals are both very good and we work in close cooperation with them.

Supplementing our first aid room, and as a means of affording the quickest possible attention in case of serious accident, each department in the mill has a first aid cabinet. The nurse in charge of the first aid department is held respon-

sible for keeping these cabinets filled with fresh supplies and ready at all times for any emergency.

These dressing cabinets, in a way, may be looked upon as first line dressing stations, to be used only in exceptional cases, or at such times as the first aid department may be closed.

Safety Service and Sanitation

To protect the worker from getting injured receives more time, thought, and energy than care for him after he is injured. Our safety department is under a trained safety director, whose duty it is to keep informed of the latest rulings on the most approved safety methods. It is also his duty to study plant conditions and to see that all hazardous places are guarded. The utmost care is given to his work.

Bulletin boards are placed in prominent places in every department of the mill. Excellent bulletins on safety are furnished us by the National Safety Council, and are posted on all bulletin boards. All machinery, motors, belts, etc., are fully protected by mechanical guards. A special department is maintained in our machine shop for the manufacture of safety devices.

We have our own safety council, composed of committees, the members being the superintendents, foremen, and workers from the plant. This council holds monthly meetings on safety problems. From the council are appointed traveling safety inspectors, whose duty it is to make an inspection of each department and check up on safety work. Reference to the chart showing graphically results in reduction of accidents during years 1916, 1917 and 1918, speaks for itself (Fig. 2).

Another very important division of service

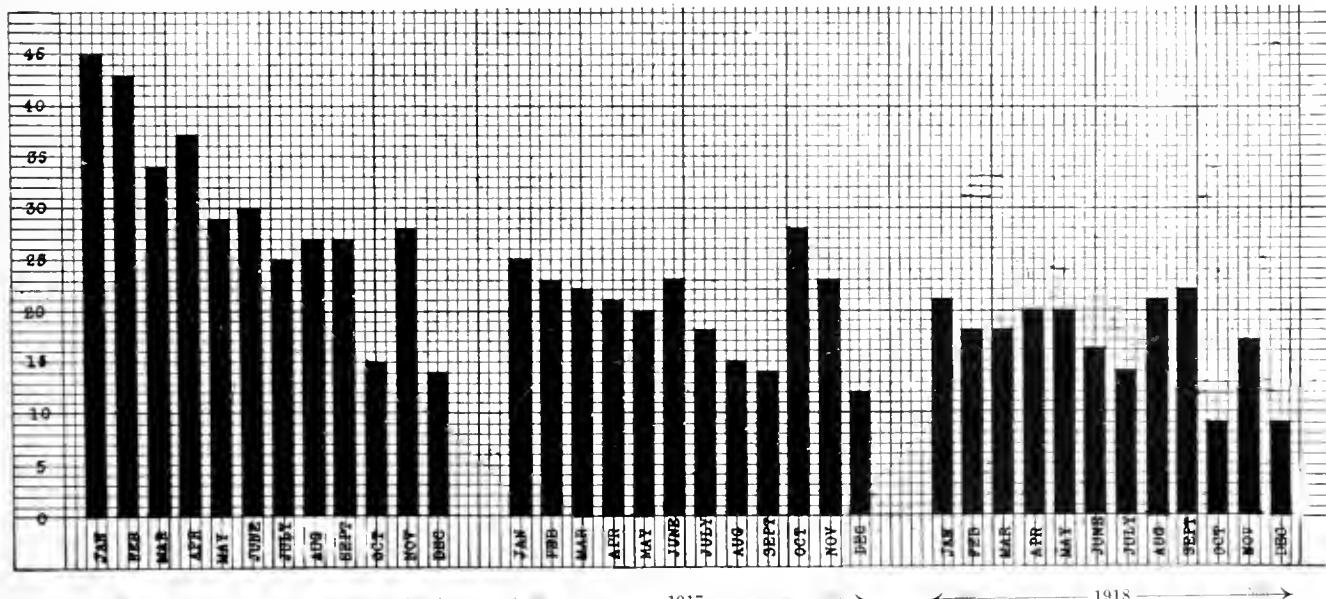

Fig. 2. Reference to this chart, showing graphically the progressive reduction of accidents during the years 1916, 1917, and 1918, as a result of the Hammermill health service, speaks for itself.

work that looms big from the standpoint of health is sanitation. Clean work rooms and a clean house in general mean freedom from disease. We have sanitary drinking fountains, lavatories, shower baths, and clothes lockers, and every effort is made to keep them in good condition. Also,

best quality of food is furnished. We want our restaurant to be a reflection of the spirit of the concern, and it serves its function if it helps to make healthy, happy, and contented workers.

Home Visiting of Absentees

It is in the home of the worker that we can get to know him better, and he can learn to know us. Real health service can be done in the home and the worker's family responds readily and appreciatively, if approached in the right way.

The success of this work lies solely in the hands of the one selected to visit in the homes. I want to lay particular stress on this point. It is of great consequence, as the wrong person may do great harm. Unless the home visitor has the proper mental attitude towards the job, and a real conception and vision of what it is all about, he or she will fail of accomplishment. We feel we have been very successful in this work, due largely to the type of workers we have selected to do it.

A graduate nurse alone is not sufficient. This qualification is essential, but only so far as it will help in diagnosing conditions. Broad human sympathy, the ability to meet these people frankly and fairly, to win their confidence, and to make them feel they are giving as much as they receive; and, besides carrying our message to them, to bring back to us their point of view—these are the things that count, and lead to a better understanding.

It is my belief that comprehensive, diligent follow-up of absentees not only reduces hours off and keeps down sickness, but is one of the best vehicles we have for personal contact and for getting the cooperation of the worker.

The report of absentees is in the hands of our visitor at 8 o'clock, and we visit every absentee daily. This includes all sick or injured, either at

home or in the hospital, the worker, or members of his family. Aid of every kind is given, medical, nursing and domestic when needed.

The forms submitted illustrate the records we keep of this work, as to hours lost, reasons, etc. (Figs. 3-4). A graphic analysis of the results and data obtained through follow-up work are available also. (Figs. 5-6).

Compensation

Hammermill follows a very broad policy with reference to employees who may become injured while in the service of the company. Compensation insurance is supposed to provide medical and hos-

Education

Morale is an absolutely necessary asset that no organization can do without. Morale can be developed through education, and education must be an active part of every live organization's program.

Hammermill's motto, as given us by our president, Mr. E. R. Behrend, is "Teach—Don't Boss." Health conservation and health service can only be gotten across by education. Two of our most effective means of expression are through the medium of our house organ, "Hammermill Bond," and group meetings.

pital care for the injured workman; and, in addition until he is able to return to work. All are more or less familiar with it and how it works out in practice.

In many cases, under the Pennsylvania Act, especially in severe injuries requiring prolonged medical and hospital treatment, compensation falls short of meeting the full medical expenses. In the majority of cases the physician and the institution must look to the patient for whatever charges are accrued after the two weeks' compensation is cared for. It has been my experience that this usually is a great hardship to the patient. Where the compensation insurance does not cover the employee's hospital and doctor bill, if the employee is not financially able to meet the balance, the company takes care of it.

The house organ carries a written message and keeps before the personnel in this way the problems discussed above. The group meetings provide a means of personal contact and of personal message. I believe this group meeting idea is original with us, never having heard of another concern using a similar method.

The Doctor

The doctor's place in industry to-day, aside from the purely professional attractions, offers unsurpassed opportunities for service not only for the good he can do in the particular plant in which he is interested, but for the far-reaching effects of his work that will be felt in the homes and in other shops in the community, in the state, and in the nation. The whole economic structure of modern

civilization will be affected and benefited thereby.

Medical and health service is here to stay, as an important branch of industry. It seems to be the trend of things all over the country that medical examination before employment is a sound procedure, and is gaining rapidly in popularity. This means that concerns that have never employed a plant physician will be obliged to do so, either as a full-time member of their personnel, or on some part-time arrangement. Every member of society

employees responded? It is about as difficult to trace the direct, tangible results from this kind of work as it is from advertising. Yet we know, should we drop our advertising, that we would soon go out of business.

I do not know the cost per person per annum at this writing. We are now working out a system to give us these costs. This we do know, that it is producing results, big results, in loyalty, *esprit de corps*, better understanding, and more

ty will be benefited by the advent of medicine into industry. It has come to stay and its influence will be felt more and more as time goes on.

No doubt this question and some others will be in the minds of all those who may read this article. What are the tangible results? What are the costs per person per annum? How have the

FACTORS IN INDUSTRIAL PHYSIOLOGY

"A humane conception of industry demands recognition of many factors. The impairment of health and life which comes by slow and imperceptible degrees in the form of depletion of nervous energy and exhausted vitality occasioned by the strain and fatigues of industry, accounts for enormous losses to the community and to industry. With the changes that have come through the discovery of new processes, the invention of mechanical and electrical devices, the utilization of new powers, *intensity*, in contrast with *duration*, of effort, has become an increasingly important consideration. The dangers incidental to strain which arise from intensity of effort

contentment, as evidenced by freedom from labor troubles, decreased turnover, less laying off, increased production, and a more wholesome atmosphere throughout the whole plant.

We know we could no more do without it than we could do without our sales, advertising, or engineering departments.

constitute a class of evil against which it is not possible to take too great precautions. The effect of strain and intensity of effort in employment is something that cannot be gauged by the generally accepted methods of classification based upon external evidence. Visible criteria, such as age, sex, and hours, may be applied up to a certain point; then it becomes necessary to take account of other elements in the human equation, and to consider a variety of physiological and psychological reactions."—W. L. Mackenzie King.—"Industry and Humanity."

No one is useless in the world who lightens the burden of it for someone else.—Charles Dickens.

HEALTH HAZARDS AND AFFLICTIONS OF SOFT COAL MINERS

BY EMERY R. HAYHURST, M.D., PH.D., CONSULTANT, DIVISION OF INDUSTRIAL HYGIENE, OHIO STATE DEPARTMENT OF HEALTH, COLUMBUS, OHIO

THE health of employees in the coal mining industry in the United States has remained a matter of more or less conjecture. In regard to certain working conditions, the United States Bureau of Mines and associated departments have done much work upon ventilation, temperature, and humidity, particularly in respect to explosions and sudden disasters, such as asphyxia. There has been no attempt to analyze the health hazards, to detail the afflictions, or to compile the vital statistics of soft coal miners.

During the last half of 1918 the Ohio Health and Old Age Pensions Commission and the Illinois Health Insurance Commission assigned the investigation of these questions to the writer in a cooperative arrangement with the respective state departments of health. In Ohio I had the able assistance of Dr. R. P. Albaugh, director of the Division of Industrial Hygiene, and in Illinois, of Mr. Paul L. Skoog, director of surveys.

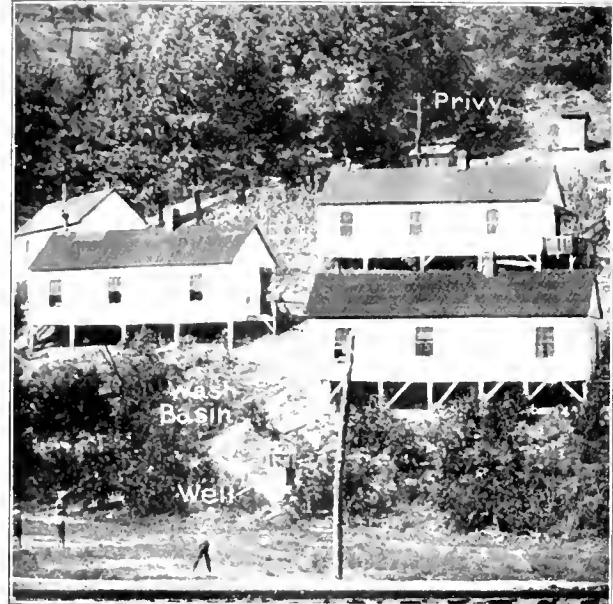

Bituminous or soft coal only is mined in Ohio and Illinois. The employees in Ohio in 1917 totaled 49,919 and produced 41,677,986 tons of coal; the employees in Illinois for the same year were 80,893 and produced 78,983,527 tons. Penn-

sylvania and West Virginia are, however, the two largest producers of soft coal. The industry, while fluctuating year by year, is constantly on the increase, and the coal in sight in each state is enough to last for several centuries, allowing for stable increment in the rate of mining. The coal fields of Ohio lie in the eastern third of the state and comprise thirty of the state's eighty-eight counties; those in Illinois begin at La Salle, in the northern third of the state and extend to the state's southern counties, where the big fields exist, and comprise fifty-one of the 102 counties. In both states the coal fields are divided into twelve districts. An itinerary for field inspections was arranged which covered all districts in both states, during the summer of 1918. There were forty-three mines visited in Ohio, employing 6,072 men, and fifty-six mines visited in Illinois, employing 15,809 men. In addition, many mining towns were inspected and persons interviewed by a pre-arranged questionnaire, including twenty-three mining physicians in Ohio and fifty-three in Illinois. Mortality statistics were compiled principally from the records of the United Mine Workers of America at Springfield, Illinois. The

A multiple-tenement dwelling of concrete construction in the type of architecture that is recommended by the United States Bureau of Mines as a desirable pattern for homes in mining towns, to replace the insanitary shacks which have housed the families of miners in so many localities. The apartments are of five rooms each, and are fitted with all modern conveniences. The photograph was taken at Gary, Ind.

investigation also covered typical examples of housing conditions and the methods used in mining communities to cope with sickness and death. We traveled by automobile principally. Selection of mines to visit was made so as to include those of large, medium, and small production and those adjudged by mine inspectors and others to be

good, fair, and bad in respect to working conditions.

Mining Conditions

Ohio is the older producing state and is a district of shallow mines with the drift type of entrance predominating. The deepest mine is 275 feet. Of 1,207 operating mines, but 168 employed more than 100 men, the largest employing 488 men (Webb Mine in Belmont County). Illinois is a district of deep mines with the shaft type of entrance almost universal. The deepest mine (at Assumption) is 1,004 feet. Of 810 operating mines, 286 employed more than 100 men, the largest employing 969 men (mine at Orient in Franklin County).

The room-and-pillar type of development characterizes Ohio mines and also Illinois mines, with the exception of some long-walled mining (adaptable to low seams) in the northern part of the latter state. All geological coal seams are worked in both states, but two or three seams constitute the principal producers. The distance to the working face from the entrance in older mines reaches approximately five miles in Ohio and as much as three miles in Illinois mines. Both steam and electricity are extensively used for power,

but terminal haulage in bigger mines and motive power in smaller mines is usually by mules, horses, ponies, or man power. Mining machines cut 85.7 per cent of the coal mined in Ohio and nine-tenths of the workers are employed in machine mines. On the other hand, in Illinois, mining machines cut 60 per cent of the coal produced, while 13,957 men actually work with mining machines. The balance of the coal is produced by pick miners.

Animal barns are located more below ground in Illinois than in Ohio. Black powder constitutes the chief blasting substance, although considerable "permissible" powder (a safer form) is used in Illinois, and dynamite, in both states, for the blasting of rock. All "shooting" is done by shot-firers after work hours in Illinois mines, but is done, as a rule, by the miners themselves during work hours in Ohio mines. Ohio mines are, as a class, wet mines and are quite cool and often muddy under foot and dripping from overhead. Illinois mines are dry mines, the deeper ones rather warm, and sprinkling of roadways is much resorted to in order to prevent explosions from following along dust courses.

Mine Gases

The chief mine gases are of three types: fire damp (methane, CH_4), which is explosive but not dangerous to health; black damp (where carbon dioxide and nitrogen are increased at the expense of oxygen); and white damp (carbon monoxid). The first two "damps" occur naturally in mines, and artificial ventilation, which is promoted by means of large blow fans or furnaces, as a rule, is necessary to keep these gases sufficiently diluted to prevent explosions and to supply enough oxygen to the workmen for breathing purposes and for the burning of lamps. The state mining laws are very specific on the details of this artificial ventilation of mines and through the inspection system and the employment of mine examiners by the operators, a high degree of ventilation perfection is usually maintained. Small mines use natural ventilation with success. Certain mines in both states tend to produce fire damp, particularly southern Illinois, and many explosions occur; but, on the whole, mining men state that none of the mines in either state are particularly "gassy" (meaning fire damp). Unlike many British mines, no mines in either of these states have to be worked by safety lamps exclusively. White damp occurs in mines in connection with fires and explosions and the blasting of powder when the air supply is insufficient. It is always the result of incomplete combustion. It is the dangerous component of "after damp" which occurs

cers after fires, etc., and which has rather more effect on canaries or mice than upon men, so that the former have been used as test animals. The collections of this gas are insidious and the miner has no ready means of detecting it. Many Ohio miners suffer from it because of the constant shooting which is allowed during working hours. "Feeders" or "blowers" of illuminating gas, such as is used for domestic purposes, are little known in either state. Gasoline locomotives, such as exist in some Illinois mines, are not allowed in Ohio mines, principally because of the pollution of the mine air by the dangerous exhaust fumes characteristic of gasoline motors.

Miners usually work two in a room, or at least in pairs, in two or more rooms, and an especial feature of ventilation is to split the air currents entering the mine so as to pass fresh air in a method of even distribution to these work rooms. The laws require that no men be allowed to work in rooms or advancing entries more than 60 feet "ahead of the air," which means the distance from a definite air current of given volume. An effort is made to keep this air current equal to 100 cubic feet (150 in Ohio) per man per minute (with 50 cubic feet increase in "gassy" mines) and 500 cubic feet for each animal.

The temperature of mines is very constant. Shallow or wet mines are the coolest (temperature falling between 50 to 60 degrees at the working face). Mines between 300 to 600 feet deep have temperatures ranging from 60 to 70 degrees.

strata. Hence, the physical condition of mine air, with the exception of dust, is ideal for work. The chemical condition is rendered so through close obedience to the mine laws on ventilation.

Other Factors About Mining

Practically all mines are infested with rats or

Alternation of good and bad roof, illustrating the plan of timbering to support the "loose ground."

mice, sometimes both. In the absence of epidemics such as plague, they have little significance as a health hazard to miners. Insects in mines exist only as gnats or small flies, few in number and consequently of small menace. Mosquitoes invade drift mines for a few score of feet only. When sanitary privies are absent on the surface, which is the invariable rule, these and other insects are a great menace as carriers of disease from excrement to food in the homes of the miners.

Over nine-tenths of all miners work under ground. The eight-hour day is universal, although some company men may work as long as ten hours. Overtime is very infrequent. Small night shifts are employed at some big mines. Absenteeism averages about 10 per cent per day, and this percentage is about doubled for a day or two following pay day, which occurs twice a month. Injuries cause about 2 per cent of total absences. Labor turnover is much more pronounced in large mines and mining centers, and amounts to from 2 per cent to 30 per cent per month.

In the large producing districts in both states foreigners make up from 70 per cent to 90 per cent of the employees. These consist of eastern and southern Europeans. Colored employees are found in small numbers and then only in a few mines. Englishmen are numerous in some older districts.

An inquiry into the ages of 4,793 employees in Ohio and 13,889 employees in Illinois showed 0.6 per cent over 70 years of age in Ohio, 0.2 per cent in Illinois; 2.7 per cent between 60 and 69 in Ohio, 3.5 per cent in Illinois; 87 per cent be-

726

Chute in panel longwall mine, in dipping seam of a coal deposit.
(Photo by H. I. Smith, United States Bureau of Mines.)

Slight seasonal variations occur. The air always increases in temperature as it passes through the mine. The humidity of mine air is invariably high, since even air carrying minimum amounts of water vapor into the mine, as in the winter time, still leaves the mine nearly saturated, because of moisture absorbed out of the coal and

tween 22 and 59 in Ohio, 89 per cent in Illinois; 9.7 per cent between 16 and 21 in Ohio, 7.3 per cent in Illinois.

It was found that for the past two years mines have been working very steadily and that during the past year shortage of railroad cars for hauling coal away constituted the chief cause for shut-

Three-room miner's cottage at Dewmaine, Ill.

downs. Occasionally epidemics of influenza limited a mine for a few weeks here and there. At the present writing, reports show that mining districts have been hit severely by the influenza epidemic—many mines shutting down entirely. Celebrations and funeral observances cause shutdowns of a day at a time at most mines several times a year, in some respects the large mines suffering the greatest frequency of these. While sickness could not be discovered as a cause, still the part-days taken off by great numbers of workmen are likely more in the nature of health necessities than is usually thought.

Transportation to and from mines is often very difficult, particularly in Ohio districts, and workers suffer hardships and loss of time in consequence.

Old-style, cheaply constructed and neglected company houses in which miners' families live.

The mine inspection system of the state is chiefly concerned with the preventing of accidents, especially explosions, fires, and asphyxiations. While the inspection system is plainly short of man power in both states, especially Ohio, this provision for coal mines redounds as much to the general health as to the prevention of the disasters

mentioned, since ventilation is a chief part of the inspection system.

Wages were good at the time of our inspection and with the present steady work, the pay envelope is large, while poverty and pauperism are practically unknown. In previous years, because of extensive strikes and because of the lack of demand for coal, most mines have been shut down for many months every year. In Illinois, the Springfield Survey in 1915 found that many mining families had great difficulty in making ends meet throughout the year. Evidence is to the same import in Ohio. Competition has undoubtedly been too keen in the past and coal sold too cheaply at the mine.

The Special Health Hazards

Dust.—This stands as the chief ban of coal mine air for the vast majority of miners, and, speaking from a health point of view, its varying composition from coal dust to granite dust is in proportion to its danger to health. Pick miners, machine men, and loaders (*i. e.* workers at the face), and tipple men are especially exposed.

Illumination.—Illumination is no longer a hazard for miners, since much of the bottom is supplied with electric lights and miners use the modern carbide lamps. Oil lamps are all but gone. Safety lamps, fortunately, with their imperfect illumination, are not required in our mines.

Heat.—Miners are not exposed to high working temperatures. Steam hoisting engineers may have undue exposures. Temperature in Illinois' deepest mine may run up to 80 degrees F., but usually workers are subject to less than 70 degrees F.

Cold.—The temperature of mines is invigorating. As long as workers keep active, the rather low temperatures, of themselves, are no hazard.

Humidity.—Dripping roofs, mud, and dampness characterize most Ohio mines. Dryness characterizes Illinois mines under foot, but the atmosphere is usually nearly saturated with moisture.

Fatigue.—Faulty postures and work of jarring, vibrative character, heavy lifting and straining at times, and a certain percentage of men ill-fitted physically for this work, are the chief hazards.

Hours of Work.—The eight-hour day, with very little overtime, obtains at mines. Some company men (laborers) work ten hours.

Infections.—The disposal of stools in the gob (refuse in the mine), as is the prevailing method, can be made safe. The extent to which coal mine dust may transport virulent germs, as from spitting, has not been investigated; the

hazard is probably insignificant. Diseases from animals, such as anthrax, glanders, and lockjaw, do not appear to exist. In the presence of the black plague, the rats and mice in mines would be a great menace. Injuries which miners receive are at least as free from secondary infections, if not more so, than in most classes of workers.

Electricity.—In addition to burns and shocks, and occasional electrocutions, the witnessing of brilliant electric flashes occasions some electrical ophthalmia—a painful swelling of the eyes which may persist up to several weeks.

Poisons.—These concern mine gases almost solely (see above). Sulphur occurs as pyrites and

Wash basins and shower baths in the large wash and change house at an Illinois mine.

in acid forms, the latter dissolved in water and often strong enough to eat holes in clothing or to cause ulcers in the eyes if gaining access to them.

Assuaging of Thirst.—Questionable water supplies in many instances render miners liable to typhoid fever, dysentery, and water-borne diseases. Alcoholic beverages are not permitted while at work.

Personal Hygiene.—Miners are in great need of instruction in matters of personal hygiene and the prevention of sickness. A large number of miners' illnesses could be curtailed by this means.

Wash and Change Houses.—Unlike Illinois, few mines in Ohio are equipped with wash houses or change houses. This feature is emphasized by a state law in Illinois for all industries. Here and there in Ohio a few men group together and build and equip a shanty. Private persons sometimes do this and a charge of 25 cents to \$1.00 per month is made for their use. The workers supply soap, towels, and lockers. Shower baths are frequent in Illinois and are considered the ideal ablution. In Ohio, empty powder cans, tubs, or basins are the rule. Hot

water is apt to be absent at electric mines. By tradition, miners bathe completely every day where opportunity is afforded. This means that in Ohio he usually does it at home. Often he builds a shed in his yard in which to wash. Statistics show that properly equipped wash houses at mines are used by upwards of 90 per cent of the employees. The absence of a place at the mine in which to wash up, after work, was commented upon by many physicians as a potent cause of the rheumatism, colds, and pneumonia which prevail among miners.¹

Clothing Provisions.—Where wash houses are present, provisions for keeping work clothing and street clothing are at hand. The ideal arrangement is a room partitioned off from the wash quarters, equipped with ceiling hooks (hangers) for work clothes and lockers for street clothes. Too great crowding was a common observation, and nails or pegs driven into the walls of a shanty was also common.

Water Supply.—Water for drinking purposes is usually not obtained at the mine but is brought by employees in their lunch buckets. Wells in the neighborhood of mines, often in very poor sanitary condition, are the usual sources of water for drinking purposes. In the malarial districts, for instance, the open-top wells with bucket and rope prevail. Scarcity of water is serious in some districts. Undoubtedly, much typhoid fever, dysentery, and other sickness in mine districts are due to lack of attention to the source of supply of drinking water. Hydrochlorid disinfectants could be provided at small expense at every mine.

Sewage Disposal.—Mines do not have toilet facilities below ground. The men at work simply use the gob piles. In dry mines there is little hazard from this practice, provided care is taken by each miner to cover his stool. In many mines portable trench buckets, or closets mounted on trucks, could be used. At the surface, where from a few to fifty men are always employed, the vast majority of mines provide nothing in the way of a latrine, much less a sanitary one, for the workmen. Instead, the latter usually seek the neighboring dirt piles, fields, timber or hillsides. On account of this lack, the flies and insects about mines and mining towns are special menaces as disease carriers. A standard privy for the surface workers at a mine could be constructed at very little cost.

Lunch Provisions.—Each employee at a coal mine invariably carries his own lunch in a specially constructed miner's lunch bucket, which

¹ The Bureau of Mines has made a special study of wash and change houses in Technical Paper No. 116.

is provided with a water compartment. The thirty-minute lunch hour prevails. Occasionally workmen at the surface may have opportunity to lunch at home.

Housing Conditions and Local Health Administration

The community has a large place in determining the diseases of miners. Very often the chief afflictions are favored by insanitary housing conditions, such as unsafe water supplies, sewage disposal, and food supervision as well as lack of efficient local health administration. The attitude in America concerning community health is invariably to "put it up to" the community itself, and as long as communicable diseases are not spread to neighboring communities to an extent great enough to raise protest, very little attention is given to health by any locality. Contrary to usual belief, the rural community is quite universally the most health hazardous place in which to live.

Housing Conditions.—The hygiene and sanitation of housing are important, since housing conditions involve about one-third of the normal day for the worker and most of the time for his family. While some mines are located in, or close to cities, mining towns, as a rule, are composed of a store or two around which very plain frame dwellings or shanty houses exist. While there are some model communities in each state, model in regard to building construction and ar-

angement and upkeep, safe sanitary standards as regards both water supplies and sewage disposal were nowhere encountered. The typical mine town consists of rows of dingy houses, all built after one or two patterns, often located on hillsides, with rows of privies located close to wells or draining toward the wells on the next

street. Rarely any attempt at garbage collection exists. Often small ditches of water act as open sewers. Screens for houses are usually provided by the occupant if present at all.

At practically all mines with company houses some workers have bought or are buying their homes. The company erects them for rent or sale

Entry way of a closely timbered longwall mine.

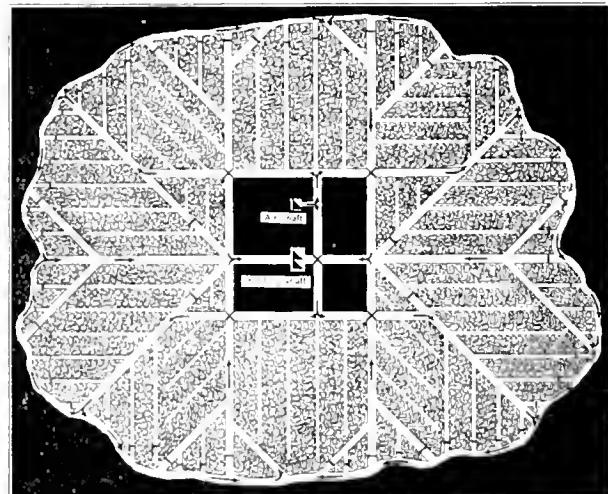

and they are sold on very easy terms to the miners. Here and there additional houses or a small town have sprung up around the company houses. Building syndicates have erected many miners' residences and rent them, receiving this rent by a check off the miner's pay at the mine. Great complaint was frequently heard of the lack of upkeep of them, even as to rendering them habitable. Miners' houses usually contain three to five rooms and are of the story-and-a-half type. Rentals average about \$2.00 per room per month. A great number of mining companies have built from four to twelve houses and then allowed the balance of the community to build up of itself.

(To be continued)

MEDICAL EXAMINER ANSWERS QUERIES

In the April issue of the *Ohio State Medical Journal* a new department is started which should be of great value in harmonizing the relationship of the physicians of the state to the workmen's compensation fund. In this department each month the chief medical examiner of the Ohio Industrial Commission will discuss medical phases of the subject and answer inquiries submitted by physicians. It has been found that many sources of dissatisfaction are due to lack of understanding of the details of the Act, including the making of reports of accidents and such follow-up reports as may be necessary.

The Ohio State Medical Association has for some time served as a clearing house of such information for the physicians and has acted as their representative in disputed matters. The new arrangement brings the physicians and the medical department of the industrial commission together.

Plan of longwall mine showing direction of ventilating current (After Swift).

rangement and upkeep, safe sanitary standards as regards both water supplies and sewage disposal were nowhere encountered. The typical mine town consists of rows of dingy houses, all built after one or two patterns, often located on hillsides, with rows of privies located close to wells or draining toward the wells on the next

EDUCATION IN INDUSTRIAL MEDICINE

AN ABSTRACT OF A PAPER PRESENTED BY A COMMITTEE OF CINCINNATI BUSINESS MEN.*
BY OTTO P. GEIER, M.D., CINCINNATI, OHIO

ON February 8th a group of some eighty citizens determined after thorough consideration of the subject, to raise a fund of \$100,000 or more to cover the expense of establishing and maintaining for a period of five years a Department of Industrial Medicine and Public Health in the University of Cincinnati. The Committee authorized by that meeting desires to place its plans before the public in the firm belief that they will lead individuals to contribute their small part towards the creation of this idea which seems to hold so much in promise for the commercial and industrial life as it relates itself to public health.

War Adds Its Weight to the Idea

The rejection by the army of more than one-third of those drafted, on account of physical disability, the tremendous opportunity for gathering accurate statistical data concerning the health of individuals in the armies of the Allies, and the fearful toll in lives from the pandemic of influenza—all these have brought home to the employer and to an awakened public the terrific economic waste of ill health.

Present Medical Teaching and Organization Inadequate

The discussion held on the evening of February 8th made it plain that medical teaching and medical organization, as well as methods of practice, have not kept pace with the tremendous industrial and commercial organization of society. It is evident that the congestion that occurs in the housing and working conditions in large cities demands a type of medical engineering and medical practice that is not now taught.

To meet the changed conditions, medical engineers—public health physicians and industrial physicians—must be specifically trained for their jobs of favorably affecting the health of large units of society. An intensive effort must also be made to socialize the viewpoints of all physicians

A plan for the establishment of a Department of Industrial Medicine and Public Health in the College of Medicine of the University of Cincinnati, to provide—

Facilities and instruction for graduate and undergraduate medical students in industrial medicine and public health, to be taught in cooperation with the industries and the local public health agencies, leading to degrees in industrial medicine and public health, and to provide—

For cooperation with the National Safety Council and Employment Managers' Association in arranging courses of study.

and to improve their economic status. A new field of endeavor for physicians has arisen. Corporations fortunate enough in the past to find properly trained, socially-minded medical men have found them invaluable in their Personal Service Departments. Nearly a year ago a group of citizens of Boston and vicinity, recognizing this same need, raised a fund of \$125,000 for a period of five years, to establish a

course in industrial hygiene at the Harvard Medical School. The responsibility for the correct conduct of this new project was vested by Harvard University in the Governing Committee on Industrial Hygiene, made up of five representatives chosen by the faculty, and an Advisory Committee of three representing the contributors. Some such plan of making close contacts with the industries and securing their assistance in further elaboration of these plans will be followed here in Cincinnati. In a number of other medical schools similar courses are under consideration.

Cincinnati Knows How to Teach

We here in Cincinnati, in our engineering college, have originated and demonstrated the value of the cooperative method of teaching. Cincinnati is prepared, therefore, in this new venture to secure, through the application of this cooperative spirit, a large return for its investment in this new department. Our plan will return good dividends to the donors, the college, the students, and the community.

Personnel.—A director and such assistants who have the knowledge and the facilities, in cooperation with the industries and the public health agencies, to teach industrial medicine and public health will comprise the personnel.

As a minimum the new department will require the full-time service of an expert physician in industrial conditions and occupational diseases,

*A committee appointed to consider a plan for establishing a Department of Industrial Medicine and Public Health in the College of Medicine of the University of Cincinnati.

a woman physician trained in sanitary science, a safety engineer, an employment and industrial relations man, a statistician, and the necessary laboratory workers and clerks. The department will also avail itself of the services of men in the medical department and teachers of other colleges of the University, as well as men in industry qualified to teach special subjects, thus enhancing the value of the course and reducing its overhead costs. It is hoped to cooperate with the laboratory personnel of the United States Public Health Service stationed at Cincinnati, and the other local health agencies.

Requirements.—The combined personnel must be familiar with the health problems of industrial institutions and the community. The staff of the department must understand the industrial, medical and surgical problems—sanitary standards of plants, occupational diseases, the subject of fatigue, general safety work; the principles of medical supervision of employees with special emphasis on physical examination, proper placement, dental hygiene and nursing service; it must have a real interest in the broad question of personal relations in industry; it must understand modern employment methods and their relation to health questions; it must be able to assist in the installation of proper employees' records, including absence, lateness, illness, etc.; it must stimulate an interest in recreation, and in food problems; it must understand the general principles and operation of cafeterias and commissaries, as well as the organization of establishment funds (Mutual Aid Associations).

These measures will be taught both by lectures and laboratory work at the medical college and through field investigations by the staff in the plants themselves.

The field work will consist of sanitary inspections of plants and of research into the special occupational hazards. Physical examinations of certain workers will be made and health instructions given to the workers. In times of epidemic the staff and assistants will be able to assist the health department in the control of communicable diseases. The students will have demonstrated to them the proper treatment of injuries and ailments. The subject of lost time from illness, injury, or other causes will be definitely related to the man's productivity and earning capacity. Scientific medicine and surgery will be continuously related to economic life.

The broad question of the existence of unhygienic working and factory conditions—the matter of inadequate ventilation, lighting, drinking water, toilet and locker facilities, as well as facilities for obtaining wholesome food, will be studied along with the occurrence of dust, fumes, gases, poisons, overcrowding, unnecessary noises, and excessive variations in temperature and humidity, some of which produce an impaired vitality and low output.

The subject of fatigue, with its relation to bad vocational placement, monotony, speed, and overtime will be weighed in as factors of inefficiency and low earnings.

All of this training will be for the purpose of better fitting the doctor to his job; to make of him a social and medical engineer as well as a physician; to make available to the mass of working men the best surgical and medical skill; to intensively educate the worker as to the dollars and cents value of good health and personal hygiene; and lastly, to give the employer accurate knowledge of the social, economic, and health condition of the worker, otherwise unobtainable. There will come to the employing class interest

IF You are giving any serious thought to the labor questions of the day:

If you believe that some concerted, intelligent effort should be made to prevent a wave of radicalism;

If you are interested in creating better relations between employer and employees;

If you recognize that ill health of body and mind are a drag on the commercial life, the industries, and the community;

If you know that 75 per cent of the economic waste from accidents is preventable;

If bad home conditions leading to disease are detrimental to the worker's value;

THEN

You will carefully read these few pages, for herein is set forth a definite plan to raise the standard of living and improve industrial relations

(1) through better community health;

(2) through safer and better working conditions;

(3) through guarding the health of the workers at the plants;

(4) through better attention to the injured.

in and greater appreciation of the value of community health and of the need for the extension of public health control.

The plan will supply the health authorities with assistance in the control of communicable diseases and supply statistics as to the occurrence of sickness not now available. A natural outgrowth of such work will be the establishment of night, diagnostic clinics for the determination of occupational diseases. Knowledge of and cooperation with the organized health and relief agencies of the city will result from the training.

Such a course will not only graduate doctors of public health and industrial medicine, but will mold opinion in behalf of preventive medicine; it will be a check on the commercializing of the science of medicine; it will discourage quackery, both medical and dental, and reduce the consumption of patent medicines, on which this country now expends a half billion dollars yearly. It will tend to democratize and socialize medicine—make the latest diagnostic facilities available to all of the profession instead of the favored few. It will raise the standards of medical practice and thus favorably affect the health of the mass of people. It will produce a group of men who can intelligently lead in sound medical and health legislation, and hasten the day when such social measures as compulsory sickness insurance can be intelligently discussed by a sufficient number of socially minded physicians and surgeons.

Plan of Instruction

As a tentative plan, the course of instruction will occupy one college year of approximately eight months. The first term will begin in Octo-

ber, 1919, and will be open to graduates in medicine.

Like the cooperative course in engineering at the University, part of the instruction will be given at the medical college and part in the industries. Unlike the engineering course, the teaching staff will work with the students in industries and assign work to them there. Studies will be made of the conditions in the factories and findings reported to the heads of industries.

Subsequently, students will be assigned to plants to work in cooperation with the plant physicians, the plant dentists, the plant safety engineers and employment managers.

Finally, each student who qualifies for the work will be assigned to some plant to serve an internship and from this time on it is expected that he will be remunerated for his services.

The National Safety Council has organized a course of fifteen lessons covering the fundamentals of safety and sanitary principles, these lessons being delivered by experts, of national reputation, from all sections of the country. As a part of this plan, an active safety campaign is to be undertaken and a local council of the National Safety Council created for Cincinnati. This course of fifteen lectures, extending over a period of fifteen weeks, will be given at the University at night.

These lectures will be available to the students at the medical college and to all of the safety engineers of the various plants in Cincinnati, as well as to the cooperative students in engineering.

The safety engineer employed under this new department would become the secretary of the local council of the National Safety Council. As part and parcel of his teaching program at the University and his field work in the industries, he would make safety inspections for the plants

HEALTH AND WEALTH CONSERVATION

Good Home Conditions.—Heredity, proper food, proper housing and living, teaching of personal hygiene.

Good School Conditions.—Physical examinations, remedying of defects, clinics.

—HEALTH EDUCATION BY SCHOOLS.

Good Working Conditions.—Hours of labor, sanitary shops, good relations between employer and employed, sufficient wage, medical and surgical care.—HEALTH EDUCATION BY EMPLOYER.

Good Community Conditions.—Clean food, milk, water: protection against contagion: sewage and waste disposal.—HEALTH EDUCATION BY HEALTH DEPARTMENT.

Good Medical Colleges.—To keep up the supply of highly trained physicians, who along with dentists, nurses, hospitals, institutions, and clinics, care for ill health since the first four agencies fail to produce 100 per cent results.

The Committee believes that too little public attention has been given to "Good Working Conditions" and that the plan proposed will care for this oversight while favorably affecting the fifth factor, "Good Medical Colleges."

A TENTATIVE CHART OF THE WORK OF THE
COURSE IN INDUSTRIAL MEDICINE AND PUBLIC HEALTH

COOPERATING WITH THE

LOCAL CHAPTERS OF THE NATIONAL SAFETY COUNCIL AND EMPLOYMENT MANAGERS' ASSOCIATION
EXTENSION WORK

EXTENSION WORK

Public Service and Association Work

Director active in the work of Public Health Division of Council of Social Agencies

Assists health officers in event of epidemics

Gathers medical statistics from industries

Acts as executive secretary of Local Employment Managers' Association

Acts as executive secretary of Local Chapter of the National Safety Council

Through local chapter, renders assistance in general accident prevention campaigns

Service to Local Plants

Special research

Surveys of sanitary conditions, occupational diseases, etc., at the request of the plants

Installs medical departments

Prepares health leaflets

Encourages the installation of Employee's Service Departments

Advises and consults with employment managers

Makes special investigations and recommendations

Organizes employment departments

Confers with management as to policies

Advises and consults with safety engineers

Organizes accident prevention work

Makes investigations and recommendations

Gives course of fifteen lectures on "Accident Prevention" to safety inspectors, etc.

Gives course of eight lectures on "Industrial Relations" to plant executives. (All lectures available to engineering students and others interested.)

The PERSONNEL

Medical Director

(in charge of course)

Woman Assistant

Research Worker

Part Time Dentist

Employment and Industrial Relations Man

Safety Engineer

National Safety Council

(furnishing speakers of national reputation)

TRAINING INDUSTRIAL PHYSICIANS

Teaching at the College Cooperative

Teaching in Medicine

Places students in industrial medical departments and conducts research work in the plants with them

Supervises students during industrial internship.

Places students in employment departments and teaches them how employment records are kept and filed

Works with them in organizing "Mutual Aids."

Has students work with him in investigation and organization of accident prevention work

Students have the advantage of the circulating library and information bureau maintained by N. S. C. resulting from experience of its 4,000 members

and assist them in organizing safety work. The exhibits, slides, and moving pictures of the National Safety Council would thus be made available to Cincinnati. School and public safety work will be encouraged.

Industrial Relations Course for Executives.—In the same way the Safety Council has a course of eight lectures, extending over eight months, given by leaders in industry, especially covering the large, broad problems of industrial relations. These lectures would be made available to the medical students and to the employment managers of the various plants.

Cooperation with Employment Managers

In planning the new department, it is desirable that the man engaged to teach employment methods and industrial relations shall be selected as the secretary of the local Employment Managers' Association and that he shall arrange for and conduct a series of lectures providing an employment course for the Association.

MEDICAL CARE FOR RETURNED SOLDIERS

The United States Public Health Service has established fourteen districts through which will be handled the applications of discharged soldiers, sailors, marines, and nurses for medical service and admission to the general hospitals of the Public Health Service. A supervisor has been placed in charge of each district.

The district supervisors are charged with the administration of all matters in their districts pertaining to the admission of claimants to hospitals. It is the aim of the Public Health Service to provide medical treatment at the expense of the government for all former service men and nurses who can trace their sickness or disability to disability incurred while in the service.

Publicity is being given the work through government bulletins and other publications with the purpose of informing all former soldiers, sailors, marines, and nurses of their privileges. Applications for medical service or admission to a hospital should be addressed to the Supervisor in Charge, of the district in which the applicant resides. The application may be forwarded through the local chapter of the Red Cross or made direct to the supervisor of the district in which the claimant resides. An office has been opened in Chicago for the Eighth District, at 512 Garland Building.

LEAD POISONING—A BRIEF ON THE SYMPTOMS, DIAGNOSIS, AND TREATMENT

BY R. P. ALBAUGH, M.D., DIRECTOR, DIVISION OF INDUSTRIAL HYGIENE, OHIO STATE DEPARTMENT OF HEALTH, COLUMBUS, OHIO*

LEAD is the most frequent and important cause of industrial poisoning. It is used in its various forms in more than a hundred industries, and may occasionally be employed in every industry, sometimes under fanciful names. It is important that physicians inquire carefully as to possible industrial exposure to lead whenever certain ill-defined states of ill health present themselves. It is important also, that industrial physicians familiarize themselves with industrial processes in their plants, for unless the physician has a familiarity with such processes, the general designation of a patient's work may not indicate any exposure to lead.

Mode of Entrance Into Body.—Absorption of lead and lead compounds occurs by the inhalation of dust laden with lead, which finds lodgement in the respiratory tract, and, mixed with saliva, reaches the stomach; by way of the digestive tract by means of soiled hands, contaminated food, tobacco, etc., and in the form of vapor (finely divided oxid of lead), and as dust through the respiratory organs. Absorption probably also occurs in isolated cases through the skin. There is a great difference in susceptibility of different individuals to lead poisoning, and females are considered more susceptible than males.

Symptoms.—The symptoms of lead poisoning are varied, and in describing a typical case it should be remembered that numerous cases follow an irregular course. The disease usually appears in the chronic form and follows the absorption of minute quantities of lead over a protracted period of time. The beginning of chronic lead poisoning is insidious, with disturbances of the general health, a sense of weakness, decline of bodily strength, headache, constipation, eructations, distress in the region of the stomach, metallic taste, and fetid breath. The blue line, caused by the deposits of sulphid of lead in the gum tissue near the margin, may or may not be present. Lancinating pains, usually paroxysmal, are common, especially in the extremities, and tremor is almost constant. Typical are the paralyses, generally affecting the extensor muscles of the forearm, resulting in wrist drop. Paralyses of the extensors of the lower extremities may occur (foot drop), and, more rarely, of the flexors. There is an in-

crease of blood pressure and often a basophilic degeneration of the red blood corpuscles in severe intoxications. Nervous and mental symptoms are not infrequent and death may result from disease of the brain (saturnine encephalopathy).

Cases accompanied by severe abdominal colic are usually considered acute. The colic is usually preceded by obstinate constipation and perhaps also by loss of appetite or an unpleasant metallic taste. The colic comes on suddenly, usually with severe pain in the vicinity of the umbilicus. The abdomen is tender to the touch, although occasionally relief is obtained by pressure. Vomiting may or may not be present. Severe pain may continue after the bowels have been relieved by cathartics, and even when there is diarrhea. The pain is somewhat relieved in the course of two or three days, but painful sensations usually remain which are aggravated by pressure.

Diagnosis.—The term lead absorption should be abolished. It is misleading. It has no more standing than would the term alcohol absorption. It is, unfortunately, being used as a blind to cover up real lead poisoning. Lead poisoning exists not because there is lead in the system, but when it is not being eliminated and there are symptoms of intoxication because of it. The diagnosis may be simple, or, owing to anomalous conditions, it may be difficult. The blue line on the gums and especially the demonstration of basophilia in acute lead poisoning are of value and occur so rarely under other conditions as to be negligible. Add to the above, anemia and any of the common symptoms of intoxication (headache, loss of appetite, cramps, etc.), and the picture is complete. Acute lead poisoning may be confused with appendicitis, and, if fever is present, both should be suspected in the lead worker.

Treatment.—The treatment is largely symptomatic. Exposure should be discontinued at the slightest symptoms. Morphine may be given to relieve colic, and enemas and cathartics to relieve constipation. Potassium iodid has been found useful in chronic cases, and, in paralysis, electrical treatment, baths, and massage. The electrolytic bath has been quite conclusively proved as being incapable of removing lead from human organs and tissues, but its psychical value cannot be doubted. More important are carefully regulated standards of industrial and personal hygiene.

*This article is the first of a series by Dr. Albaugh on the common industrial poisons.

SHORTER HOURS IMPROVE HEALTH OF WOMEN WORKERS

The report of the Illinois Industrial Survey Commission which was created by an Act of the 1917 Illinois Legislature "to make a complete survey of all those industries in Illinois in which women are engaged as workers, with especial reference to the hours of labor for women in such industries," "and the effect of such hours of labor upon the health of women workers," has just appeared.

The Commission, which was appointed by the Governor of Illinois, consisted of two representatives of women in industry, two representatives of the employers, two physicians, and a chairman, who happened to be a physician.

The Commission's report is based on the intensive studies made by its own investigators in some of the industries of Illinois and a study of similar investigations elsewhere. The report details a discussion of the general tendency to shorten women's working hours as shown by study of the laws of various states, and by an analysis in Illinois itself of the employers' reports and the hours worked in their establishments. From this phase of the work the Commission interprets the tables as definitely indicating a trend in Illinois, as well as in other states, toward a shorter working day and week for women.

The statements of industrial physicians employed by numerous large concerns in the city and state were carefully analyzed. These statements are based mainly on opinions which, however, fairly well agree in the belief that a shorter working day and week is decidedly beneficial to the health of women workers.

Questionnaires Sent to Employers

Large numbers of questionnaires were sent out to employees and many personal investigations of employees in the homes were made by the investigators of the commission. One of the most interesting facts brought out by this study was what the Commission terms a "concentration of bad conditions." Workers who stand, these being mainly personal service and trade workers in hotels, department stores, etc., have worse conditions than those who sit, both as regards hours per day and per week. Of the standing workers there was a tendency for overtime to be less and for the lunch period to be shorter.

But perhaps the most interesting phase of the Commission's report deals with the study of fatigue in relation to production under varied hours of labor. Following the principles of study of industrial fatigue as outlined by Lee and Florence, it is assumed that, when all other factors can be kept constant, diminished production indicates increased fatigue of the worker. Although this is a recognized method of study, considerable care has to be exercised in eliminating possible variants, such as difference in factory management, changes in hygiene or ventilation, questions of food, etc., which might very easily change the output without any definite relation to the element of fatigue. In the few intensive investigations carried on by the Commission all such possible variables were carefully investigated and from output itself no conclusions were drawn concerning fatigue unless all such variables had been made constant.

Some of the studies reported by the Commission seem to have the accuracy of a scientific experiment. For instance, the study of the soap industry where the women in a packing room were studied under a ten-hour day and later under an eight and one-half hour day, shows a definite increase of about 10 per cent of output per hour under the eight and one-half hour day. Under the fifty-five hour week the average production per day was 42.8

cases while under the forty-eight hour week the production was 45.5 cases per day. Furthermore, production under the shorter hours held a steadier level than under the longer hour schedule, and at the end of a ten-week period production seemed to indicate a reserve of energy in the eight and one-half hour worker which had not been observed in the same women working ten hours a day.

In a corset factory study of shortened hours showed an acceleration of production such as to make a shorter week actually more productive than a longer. In a large garment factory buttonhole workers were studied under conditions which could be kept absolutely constant, and it would seem that in this department the production rate has increased so much that total output under a schedule five hours less is equal to and even greater than production under the longer hours.

Work Conditions at Canning Plant

One of the interesting facts brought out in the study of a canning room in the beef industry was that relief of monotony even in a ten-hour day by a change of occupation shows a lessening of fatigue and an increase in production. In other words, given the same group of women working ten hours a day, if some are allowed to shift their occupation from packing beef to waiting on table a part of each day, there is a corresponding diminution of the fatigue element as measured by production.

The great argument around which much of the opposition to reduced hours for women workers has arisen has been in the seasonal industries. Evidently the study of this problem caused difficulty to the Commission and yet their investigation in the canning industry would seem to indicate that when it is possible to regulate and control other conditions of factory management, the output even in the short season trade is increased by the diminution of fatigue associated with shorter hours.

In the hat industry it was necessary for the Commission to compare two different industries, a method of procedure always open to opposition in the study of fatigue. And yet it would seem from the tables and charts that in comparing two groups of workers of about the same training and experience, there is a definite, earlier diminution in output in the factory in which long hours are worked than in the short-hour factory. The height of the curve of production is reached sooner in the long-hour factory but maintains its level for a much shorter period, and toward the end of the season there is a much more rapid drop. These conclusions follow whether the study was made of the entire working force or of a selected group of experienced workers.

Other work is reported in relation particularly to night shifts and to accidents but without any conclusive value. The report, which is signed by all the members of the Commission with the exception of the two representatives of the employers, offers an interesting document in the application of scientific methods to the study of industry. While by no means as deep or thorough a piece of work as the Commission itself says it would like to have produced, it apparently represents careful investigation and weighing of evidence before conclusions were drawn.

The whole question of industrial fatigue is becoming of more and more importance, not only to capital and labor but to society as a whole. It is not merely a question of health for the individual worker; it is largely a question of health for the community.

The minority report signed by the two employer members of the Commission indicates that an open mind toward the whole problem will go a long way toward a just solution.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C. E. A. WINSLOW, DR. P. H., *Editor*

THE NATION'S HEALTH

THE syllabus of the modern public health movement prepared by Dr. Goldwater for this issue of MODERN MEDICINE is a striking reminder of the extent to which this movement has grown and of the width of the field which it now covers. A survey of the topics included in the program and a consideration of the principles of bacteriology and physiology, of chemistry and engineering, of economics and polities, which must be applied in order to carry it into execution, makes it clear that the health officer of the future needs training of a wide and fundamental character.

A comparison of the topics listed by Dr. Goldwater with the curriculum of any Class A medical school will make it equally clear that no readjustment of the medical curriculum can bring within the compass of four years what a man needs to know in order to practice both medicine and public health.

It is this condition which has led to the development of special courses leading to the certificate in public health and the doctorate in public health, designed to prepare for the adequate discharge of the complex and exacting responsibilities of the modern health official. The certificate, according to the recent report of a committee from the leading eastern universities giving higher degrees in public health, represents one year of special training for either college or medical graduates; the doctorate represents two years of special training for men or women who already hold the medical degree. The physician who has pursued one or two years of such special study has undoubtedly acquired the ideal preparation for administrative responsibility in this department of our civic life.

Army experience has awakened in thousands of young physicians the desire to serve the community in this field and the willingness to make adequate preparation for such service. There was never so excellent a chance to obtain at least a fraction of the competent health officials we so

sorely need. The one thing that is essential if this hope is to be realized is a demand from the public that when positions in the local and state health service are to be filled they shall be filled by the men who have been trained for such work and that such men when they "make good" shall be paid salaries commensurate with the service which they render.

The members of the medical profession, if they will, can exert a compelling influence for the improvement of the personnel of the state and local health service. The physician, through his close personal relations with his patients and his general position in the community, has a power far greater than that exerted by the average member of any other professional group. The work of the health authorities touches him more and more closely every year and it is of essential importance to him that his municipal and state health departments shall be honestly and efficiently and intelligently administered.

Where the physicians in any community are actively interested, collectively and individually, in the problem of an efficient public health service, few politicians care to run the risk of an unfit appointment. If there is a local physician who by special training or experience is fitted for the position of health officer he should receive the position. If not, the administration should be persuaded to go outside for a physician experienced in public health if he can be found, and, if such a man cannot be found, for a non-medical man who is trained in public health and can utilize the services of local physicians in communicable disease control, clinic service, and the other strictly medical phases of his work.

In any case however the members of the local medical profession should be active and firm against the appointment of a health officer whose only qualifications are the possession of a genial personality, a gift of fluent speech, and a friendly connection in the world of polities.

TYPHOID IMMUNIZATION OF HOSPITAL NURSES

BY HAROLD B. WOOD, M.D., DR.P.H., ALBANY, N. Y., LATE ACTING EPIDEMIOLOGIST, NEW YORK STATE DEPARTMENT OF HEALTH

TYPHOID infection of nurses is not of uncommon occurrence. The direct transmission of typhoid fever from patients to those who are acting as nurses is one of the greatest factors in the spread of typhoid fever. Even trained nurses frequently become infected by their typhoid patients, many of them contracting the disease in spite of their care in handling infectious material. Those who have charge of the training of nurses in hospitals instruct nurses in the care of the sick, but it is apparent that sufficient caution is not used to guard the nurses against typhoid fever. That further precautions need to be observed is shown by the fact that in New York state the case rate of typhoid fever among nurses in hospitals for the past three years has averaged approximately ten times the general typhoid rate for the cities of the state. Among 2,900 nurses in hospitals there were thirty-four cases of typhoid fever since the beginning of 1916. The typhoid case rate for the up-state cities of New York state in 1916 was 39.3 per 100,000 population; the typhoid case rate for nurses in the hospitals reporting has averaged 390.7. The importance of the problem of the elimination of this typhoid fever is apparent, since its prevalence markedly decreases hospital efficiency and adds unnecessary expense, suffering, and danger.

110 Superintendents Express Opinions

To collect certain data in regard to the prevalence of typhoid among hospital nurses and to learn the attitude of hospital superintendents toward obligatory typhoid immunization, a questionnaire was recently sent to the superintendents of 254 hospitals in New York state outside of New York City. Replies were received from 110 hospitals, and these may probably be regarded as representing average conditions and intentions in the northeastern part of the United States. These hospitals had just 2,900 nurses, varying between

PROTECT ALL HOSPITAL EMPLOYEES

Typhoid immunization should be required of all hospital employees.

Hospital superintendents favor obligatory immunization against typhoid, as a health safeguard for their nurses.

Typhoid is ten times more prevalent among nurses than among the general public, and hence is a discredit and a detriment to efficient hospital management.

Nurses do not receive sufficient instruction in personal hygiene and self-protection against typhoid, whereas immunization will effectively prevent typhoid fever.

two and one hundred and fifty nurses each, or averaging about twenty-six nurses to each hospital. At this rate, there are nearly seven thousand nurses now serving in the hospitals of New York state. No reply received made any reference to the number of nurses who had gone to the war, or mentioned whether the statement given was the regular staff or a reduced figure.

In the hospitals furnishing the data, typhoid fever infected seven nurses and caused one death in 1916; in 1917, there were twenty-four cases with one death among the nurses, and in 1918 there had occurred three cases before December 1. Undoubtedly, nearly all these nurses became infected within the hospitals and probably from the patients they were treating. A few exceptions are known to have occurred. This summary does not include the outbreak of typhoid fever in another hospital in the central part of the state, in which one kitchen girl and nine nurses contracted typhoid from milk coming from a farm upon which a health officer later discovered a case of typhoid fever. The superintendent of this hospital did not reply to the questionnaire. These cases, with the others, could have been prevented by the adoption of obligatory immunization.

44 Per Cent of Nurses Immunized

Data in regard to the number of nurses immunized during the past two years were asked in the questionnaire. The superintendents replied that 1,278 nurses, or approximately 44 per cent of the nursing staffs, had been immunized. Forty-seven superintendents admitted they had not immunized any nurses, even in view of the fact that six months previous to the sending of the questionnaire the attention of the value and need of typhoid immunization of nurses had been brought to their attention by the State Department of Health. In the hospitals where no nurses had been immunized there were 1,845 nurses, one of whom was ill with typhoid at the time the report

was made. In another of these hospitals there were twelve cases of typhoid among the thirty-five nurses in 1917, and no immunizations had been done. Twelve of these forty-five hospitals expressed themselves as favorable to the proposition to make typhoid immunization of nurses obligatory, yet had not availed themselves of the opportunity.

In thirteen hospitals all of their 513 nurses had been protected against typhoid fever by immunization.

The question was asked, "In your opinion, is it feasible to make protective vaccination against typhoid a definite requirement among nurses in your institution?" Fifty superintendents voted definitely "yes" and twenty-four declared "no." At three hospitals typhoid immunization of nurses is compulsory; in three it is required of nurses while taking care of typhoid patients. One superintendent thinks it advisable for nurses who attend typhoid cases, two are in doubt, and two say it is not necessary. One remarks that it is not advisable, two declare all nurses consent, five give no reply, and two dismiss the thought by saying they give little attention to the subject.

Of the hospital superintendents who hold opinions, fifty-nine declare in favor of hospitals requiring nurses to become immunized against typhoid fever, some being very emphatic. Doubtless some have been led to this conclusion because their nurses have developed typhoid fever in past years. Although typhoid vaccination is recognized by the entire medical profession as the most effective method for preventing typhoid fever, twenty-nine superintendents are opposed to making it a requirement for nurses undergoing their hospital training. Four desire to make the protection optional with the nurse.

Opinions Are at Variance

The hospitals favoring the measure are the larger hospitals having nursing staffs varying between six and one hundred and fifty, averaging thirty-one nurses; the hospitals opposing average twelve nurses, with staffs varying between two and thirty nurses. It is interesting to note that those hospitals opposing typhoid immunization had had relatively, just twice as many cases of typhoid among the nurses as had the hospitals favoring the protective vaccination. The reasons given for the assumed attitude of opposition to the requirement of immunization included the following statements: "Impossible"; "not absolutely necessary"; "we use all precautions"; "we have had no typhoid" (in a city notorious in the past for its typhoid!); "too short a course"; and "difficult to get applicants and cannot make all the re-

quirements we would like" (in view of the circumstance that last year half of the nurses in this hospital had typhoid fever). The statements from the superintendents favoring obligatory immunization are equally illuminating: "Have done it for the past three years"; "give it to all except those who positively refuse"; "will make it a definite requirement"; "require it of all nurses taking typhoid cases"; "all consent"; "yes, most necessary"; and "yes, in every institution."

Preparedness Is Best Policy

A reply to these expressed convictions would state that no method of social or commercial development is popularly adopted unless well advertised. Any method or act which conserves human health and human efficiency is a practice worthy of universal adoption. The fact that typhoid immunization prevents typhoid fever and helps to avoid suffering, death, and lost efficiency needs no further proof or discussion. Measures of preparedness to prevent or overcome dangers which may arise are advisable to adopt. The fact that a community has had no typhoid in the past is no proof that a sudden epidemic may not occur any time from an imported carrier. This accident happens frequently. Milk-borne typhoid outbreaks are not of uncommon occurrence, and hospitals should take all precautions to meet these possible outbreaks. One hospital in New York state last summer had its regrettable experience with an infected milk supply. After the typhoid outbreak has occurred it is too late to consider the protection of the hospital staff. After a nurse is regularly assigned to the care of typhoid patients, it is equally too late. Numerous instances are known where probationers have substituted for the regular typhoid nurses just for an evening and have become infected by their lack of care in the handling of infectious material and the sterilization of their hands. Instances are known where nurses have handled bed-pans and, without even washing their hands, have carried trays of food. The danger that almost any nurse or attendant in a hospital may become infected by typhoid is not remote. No hospital course is too short to permit the giving of the necessary protection to the nurses, unless it be less than two weeks.

Too Many Nurses Stricken

The danger of typhoid infection of nurses exists not alone within the hospital in which they receive their training. When they are later called to attend all kinds of medical cases and to live under all kinds of conditions in every locality, the opportunity of contracting typhoid fever from

their patients, or from typhoid carriers or through the agencies of flies, foods, milk or water, is great; it is also evident. During 1917 the occupation of the person was recorded on 708 reports of typhoid cases in New York state, and of these persons six were professional nurses and three were physicians. There are 16,800 nurses registered in the state. If the same proportion of cases in nurses to total given occupations applies throughout the state the case rate for the 16,800 registered nurses during 1917 was nearly three times that of the general public: 142.8 for these nurses, while 52 per 100,000 was the general typhoid case rate for the state outside of New York City.

Nurses Unaware of Hidden Dangers

Typhoid immunization can most conveniently, economically, and advantageously be done when the nurse begins her term as probationer. The danger of her contracting the disease after leaving the hospital, the precautions which she necessarily must use in handling typhoid patients, and the fact that she may become a potential typhoid carrier if she is not always extremely careful in her methods, should be explained to her. Typhoid immunization will prevent her contracting the disease but will not prevent her becoming a possible carrier. Extreme care in the handling of material infected by typhoid germs and the careful scrubbing of her hands after handling such material will prevent her becoming a dangerous typhoid carrier. If the subject of immunization is left to her option, the nurse, not realizing the actual dangers of typhoid and the importance of adopting every known method to prevent it, will, in most instances, neglect to obtain the protection which it is her duty to select. The need of extending the typhoid immunization to all hospital employees is shown by the fact that the baker of one of the largest hospitals recently contracted typhoid. He was undoubtedly infectious for some days before he believed himself ill.

Typhoid immunization should be required of every employee of every hospital or public institution and should be given when the employee begins service or training. It is feasible, it is practical, it is protective; and it has been voted as an advisable obligatory measure by two-thirds of the superintendents of the hospitals in New York state.

MISSIONARIES PROVIDED MEDICAL SERVICE

The Methodist Episcopal Church has established a medical department in its missionary branch which will supply medical attendance to missionaries either abroad or at home. In future each individual entering upon a life of missionary work will be subjected to a physical exam-

ination to determine whether the candidate is in sound health. Since the church invests from \$20,000 to \$50,000 in each missionary during his life time, the new plan has been devised as a means of knowing whether the candidates are "good risks." The department has been placed under the supervision of the Board of Foreign Missions. J. G. Vaughn, M.D., formerly of Nanchang, China, is executive secretary of the new department. He has established a headquarters at the offices of the Missionary Centenary, 111 Fifth Avenue, New York City.

NURSES PAY HOMAGE TO LEADER

To the late Miss Jane A. Delano, who died in France, April 15, at the American Base Hospital No. 8, at Sauvigny, the nursing fraternity pays homage as the leader in recruiting more than 30,000 nurses under the direction of the American Red Cross, for service with the Army and Navy after the United States entered the world war.

Miss Delano served three times as president of the American Nurses' Association and was for several years was the head of the directorate of the *American Journal of Nursing*.

She was chosen for chairman of the committee in charge of developing a nursing reserve for the Army Nurses Corps in 1906, at the time the American Red Cross entered into an agreement with the American Nurses' Association to create such a reserve. She continued with the work till the time of her death.

She was born at Watkins, New York, in 1862. Her father was killed in the Civil War, and she was reared by her grandfather, a Baptist clergyman.

AID CHILDREN—ABATE CRIPPLE PROBLEM

Among 4,186 cripples in the city of Cleveland, it is learned that one-eighth of them incurred their handicap through infantile paralysis, while among children, the proportion is one-third. These are two of the outstanding facts disclosed by a survey of all the cripples of the city, in 1916, a report of which has been published by the Red Cross Institute for Crippled and Disabled Men, under the title, "Education and Occupations of Cripples, Juvenile and Adult."

The survey was reported by Miss Lucy Wright, formerly general superintendent of the Massachusetts Commission for the Blind, and Miss Amy M. Hamburger, formerly associate director of the Social Service Department of the Massachusetts General Hospital. The survey was conducted under the auspices of the Welfare Federation of Cleveland.

An effort was made to give practical guidance in formulating a community plan for promoting the welfare of cripples. Eight general conclusions are presented.

"The problem of the crippled population," it is stated, "is first of all a problem of child welfare. Although adults were more numerous than the children—more than three times as many—a fourth of the crippled population were not only under the age of fifteen at the time of survey, but a third of the adult cripples became disabled while under the age of fifteen. Thus a total of 40 per cent of the whole group were disabled in childhood."

"As a children's problem it is essentially a medical-educational one."

Two principal recommendations are given: First, that adequate provision be made for medical-educational care of crippled children. Second, that measures be adopted for safeguarding the interests of adult cripples.

THE FOURTH GREAT PLAGUE—DEFECTIVES

BY MARIAN K. CLARK, CHIEF INVESTIGATOR, BUREAU OF INDUSTRIES AND IMMIGRATION, NEW YORK STATE INDUSTRIAL COMMISSION

THE old time fallacy that "all men are born equal," with which civilization has been satiating its uneasy conscience for centuries, is as unjust and deluding to humanity as a mirage that lures the unwary traveler to certain destruction.

Whether it be the political insurgent or the socialistic "uplifter"; the demagogic agitator or the bolshevist destroyer; the religious enthusiast or the pessimistic agnostic, when they advance the false premise that "all men are born equal," their arguments one and all spell defeat from the start because they have no basis for a logical demonstration of their thesis, and no foundation upon which to rear the structure of their dreams.

There can be no equality either of opportunity or of competition in a struggle for existence between the fit and the unfit; between the offspring of the sane and the insane; the normal and the feeble-minded; the moral and the criminal; the employable and the unemployable, or the tainted and the untainted, with all of their immeasurable dissimilarities and ever increasing disabilities.

States Should Know Their People

A nation must regard itself in danger when its population consists in large part of broken-down and defective humanity, and individual states should know something about their populations before the percentage of their civic dependents is forced upon the public notice from purely economic causes.

A special commission reported to the Governor of New York in 1912 that "during the past fifteen years from one-sixth to one-quarter of the total State budget has been spent for the maintenance and care of its dependent and defective classes, one-third of whom are aliens." Since that time as a result of the increase in population in these institutions and the higher cost of maintenance a conservative estimate places the expenditure at one-fourth of the entire appropriation, the tentative estimate of which for this year amounts

The fate of a nation that fosters in its citizenship a steadily increasing proportion of insane, feeble-minded, epileptic, and physically or mentally defective persons, mostly of foreign extraction, is a matter to cause deepest alarm.

The children of foreign-born defectives reproduce and propagate the tainted family strains bred of deficient ancestry and parentage.

The cost to heredity of alien defectives now in the country cannot be estimated in terms of money. Close medical restriction of immigration will correct and prevent the evil.

to \$96,858,064.49. The object of this paper will be to discuss the immigration problem from the standpoint of the established relationship of the indigent to heredity, as well as to point out that through the admission of excludable alien stock an inequitable burden of unfit defective and criminal dependents is created.

The new immigration law excludes persons who have had one or more attacks of insanity

at any time previous to landing, as well as persons of constitutional psychopathic inferiority, and chronic alcoholics. The law is also broadened to exclude mental and physical defectives irrespective of their financial condition or ability to earn a living. The enforcement of these provisions will have a far reaching effect provided that the law itself is not abrogated by the issuance of "rules and regulations" permitting these excluded classes to land under bond in the discretion of the Commissioner General of Immigration, or with the approval of the Secretary of Labor; but even this grant of discretion does not warrant the acceptance of a bond for an idiot, an epileptic, or members of other classes definitely and finally excluded by the terms of Section 3 of the Immigration Law.

For many years the indiscriminate admission of excludable aliens into the country through the medium of inequitable and unenforceable bonds, has created results which to-day impose a staggering financial burden on the State of New York and, what is of exceedingly more vital importance, an almost unsolvable social problem, because of the transmission of those human, inheritable traits that so positively beget an insane, imbecile, feeble-minded, and criminal offspring in long and unbroken lines of descent.

An able bodied, physically fit, morally stable, and mentally alert immigrant is an asset to our country. The economic value of such an alien increases as he becomes a producer and consumer. As a defective he is a liability; if he propagates

his kind he may become a distinct menace as well as a financial burden of no mean proportions.

There is no problem of more vital importance to this nation to-day than the effect upon heredity of the blood introduced through immigration during the past decade for, while the economic burden of caring for those aliens who become public charges has even now reached enormous proportions, the chief danger lies in the transmission of such traits by the marriage and reproduction of feeble-minded, epileptic, criminal, drug-addict and borderline cases which remain at large.

What incredible folly for a government to admit such strains under any conditions! How can a nation be so blind to its future existence? In the case of New York with its three millions of alien residents, the obligation to correct and regulate this menace becomes at once an economic, social, and moral duty to the State, the taxpayer, the individual, and posterity itself.

The Federal government has the sole authority to admit, deport, or exercise discretionary power for the admission of otherwise excludable aliens; while at the same time it disclaims any future responsibility for the maintenance of such insane, imbecile, feeble-minded, diseased or public-charge cases after they are released from Ellis Island. This evasion of responsibility has placed an exceptionally heavy burden upon the institutions of New York, for the reason that that State annually receives for permanent future residence one-third of the total immigration into the United States; and an average of more than two-thirds of all excludable aliens admitted into the country.

Looking backward for a period of six years, it is to be noted that in 1912 there were admitted to the United States under bond by the immigration officials, 914 aliens, of whom 716, or 78.3 per cent, entered the State of New York. In 1913, of 678 so admitted, there were 381, or 56.2 per cent, who entered New York. In 1914, of 905 so admitted, 595, or 65.7 per cent, entered New York. In 1915, of 1,874, 1,286, or 67.6 per cent; in 1916, of 2,264, 1,482, or 65.4 per cent; and in 1917, of 2,408, 1,681, or 69.8 per cent, were released at the port of New York.

From a survey of the past twenty-five years the reason for the crucial financial situation of the present not only is apparent, but it may be demonstrated that the detrimental effects through heredity can not be estimated in terms of money.

Beginning August 1, 1914, the Federal government suspended deportations to belligerent countries and as a result we are confronted by the following alarming facts:

August 1, 1914, to June 30, 1915—Total of deportable aliens admitted to the country 1,328, of which

388 were insane; excludable at time of entry 697; other causes prior to landing 167; loathsome or dangerous diseases 76.

July 1, 1915, to June 30, 1916—Total 856 deportable aliens were admitted; insanity 394; excludable at time of entry 329; other causes prior to landing 90; loathsome diseases 43.

July 1, 1916, to June 30, 1917—Total 694 deportable aliens were admitted; insanity 346; excludable at time of entry 201; other causes prior to landing 127; loathsome diseases 20.

July 1, 1917, to June 30, 1918—Total 1,045 deportable aliens were admitted; insanity 595; excludable at time of entry 215; other causes prior to landing 179; loathsome diseases 56.

We have therefore for the four years 1914 to 1918 the astounding total of 3,923 excludable aliens upon whom orders of deportation have been suspended, and of this number 1,723 were insane, 2,005 were excludable from other causes, as liable to become public charges, and 195 suffering from loathsome or dangerous diseases.¹

Mental Deficiency and Dependency

It has been demonstrated conclusively that the vast majority of dependent aliens in the State of New York are directly or indirectly chargeable to the iniquitous practice of admitting such prohibited classes under bond, but during the four years from 1914 to 1918, even this discretionary power was exceeded and many of them were admitted on their own recognizance, which, after all, is perhaps as binding and effective as the other unenforceable method. The fate of a nation thus fostering a broken-down and defective population either from blood taint, eugenic causes, or accident casualties, and with a gradually increasing percentage withdrawn from productive lines, is to be regarded with alarm.

In order to ascertain the extent of institutional care of the insane, feeble-minded, epileptics, alcoholics, and drug addicts in the several states in the Union, the National Committee for Mental Hygiene, on January 1, 1917, took a census of the patient population of institutions caring for these classes throughout the country with the following results:

CENSUS OF INSANE

There were 234,055 insane patients under treatment in institutions in the United States on January 1, 1917. Of these 225,824, or 96.5 per cent, were in public institutions, and 8,231 in private hospitals.

CENSUS OF FEEBLEMINDED

There were 37,220 feeble-minded persons in institutions throughout the country. Of these 34,404, or 92.4 per cent, were in public and 2,816 in private institutions.

CENSUS OF EPILEPTICS

The epileptics, not including those insane or feeble-minded, totalled 10,801. Of these 10,394, or 96.2 per cent,

¹ Table XVIII—A. Reports of Commissioner General of Immigration, 1915; 1916; 1917; 1918.

were cared for in public institutions and 407 in private institutions.

CENSUS OF INEBRIATES AND DRUG ADDICTS

The census showed a total of 4,891 inebriates and drug addicts receiving institutional care. Of these 3,991, or 81.6 per cent, were in public institutions.

The census illustrates that of the total number of insane, feeble-minded, and epileptics in the United States, 95 per cent are being cared for at the expense of the government.

The population of the United States increased from 91,972,266 on April 15, 1910, to 102,826,309 on January 1, 1917, an increase of 11.80 per cent, while the insane in institutions increased from 187,791 to 234,055, an increase of 24.64 per cent during the same time, which was the period of heaviest immigration in the history of the country. Recognition of the necessity for the study of eugenics as a governmental function has not yet been seriously considered, but in the State of New York, groaning as it is under its ever increasing cost of public charges, neglect of this subject is little

short of criminal. While experiments in various municipalities have been conducted with the hope that the feeble-minded could be trained to be self-supporting in the majority of cases, failure has resulted. It has been conclusively demonstrated that the feeble-minded child will remain feeble-minded; also it is true that insane tendencies are hereditary and that crime and pauperism are traits just as inheritable as are habits of thrift and industry. The recognition of these facts demonstrates that if we are to retain our national stability an amendment must be read into the immigration laws of this country, providing for the mandatory exclusion of all unfit and defective aliens, and to assure the survival of the fittest, the expeditious deportation of all of those who have become dependents within the five-year period. In no other manner can be effectively safeguarded "our lives, our liberty, and our sacred honor." Far better an illiterate, able bodied alien whom we can instruct at little cost in time and money, than a defective whose traits will be transmitted to posterity either before he becomes a public burden, or, if he escape incarceration, he becomes a vastly greater menace by

begetting of his kind—the worse evil of the two.

Experiments conducted and data collected by the Carnegie Station for Experimental Evolution demonstrate that a great majority of the feeble-minded spring from defective stock, and, indeed, that the mating of certain classes of defectives will produce very definite types of offspring; as well as the indisputable fact that from degenerate communities spring forth a large proportion of the paupers, beggars, criminals, and prostitutes that infest our cities.

While the subject of alien dependents in the civic institutions of New York has been treated exhaustively by many agencies these investigators have, usually, confined their reports to their own special field of endeavor such as that of the State Hospital Commission, the State Board of Charities, the State Superintendent of Prisons, and the Committee on Inquiry into the Departments of Health, Charities, and Bellevue and Allied Hospitals (1913).

As an immigration problem it has become the function of the writer to correlate the data compiled by these various agencies, and the result has engendered a very definite conviction that it is imperative to attack the problem at once, at the source, as well as to utilize all of the scientific and governmental resources at our disposal to prevent the spread of a scourge more insidious than any of the exterminating plagues of history. A lack of consideration of the innate qualities of our immigrants is perhaps the greatest evil that threatens our civilization.

Defective Aliens Intermarry

A noted scientist asserts that "it is probable in the case of a feeble-minded immigrant that because of the fact that he cannot select a normal stock in which to marry, he will therefore marry another of his kind, and as a result all of his children, grandchildren, and great grandchildren will be feeble-minded." In 1912 it was reported that there were 7,000 feeble-minded children in the schools of New York, 30 per cent of whom were of alien extraction. Since that time the ungraded classes have multiplied and reports of experiments conducted by institutions and reformatories are discouraging in so far as success in efforts either to

make such ungraded pupils self-supporting or to correct their unmoral tendencies as a class. Abundant illustrations are available certifying that families of defectives and criminals can be traced back to a single ancestor. The transmission of "Huntington's Chorea" through a series of families involving 900 persons, all of them afflicted with anti-social traits, has been definitely traced to the source of three brothers who came to New England in the seventeenth century.

Heredity and Defectives

Nearly always the preponderance of such strains as a result of consanguineous matings are concentrated both as to traits and localities, and for the sake of illustrating the danger to heredity through the introduction of such defective aliens, it is permissible to cite two well known cases: "The progeny of Bell Juke is a dreary monotony of harlotry and licentiousness to the fifth generation," which cost the State of New York more than \$1,700,000 in 70 years; and the Nam family, which has imposed a financial burden of \$1,500,000 during the same period, "not directly in the care, but indirectly, in the damage they have done."

Ishmaelites of Alien Extraction

Among other cases where whole colonies of defectives spring from a single ancestor we have as illustrations the "Ishmaelites" of Indiana, whose descendants are to-day intermarried with more than 200 other families who have begotten murderers, prostitutes, and a large number of illegitimate. In Rhode Island there exists a whole colony of deaf mutes—the result of consanguineous matings of defective and related strains.

In Kentucky there is the Owen family. From the original four children has sprung, since about 1850, a total of 1,750 individuals, among them 121 prostitutes, with a long criminal record and a number of murders.

Extreme examples such as the above are necessary to drive these incontrovertible facts into the public consciousness and to illustrate the utter recklessness of permitting the admission into this country of feeble-minded, epileptic, insane, and imbecile immigrants who, together with their progeny, eventually reach the hospitals, almshouses, and prisons of the State.

The fact that the number of feeble-minded in the country greatly exceeds the number of insane as well as the fact that there are fewer of this class of defectives in institutions in every State in the Union, but accentuates the danger from a eugenic point of view.

With such a nucleus as the investigations indicate, and mindful that the admission of even

one feeble-minded person represents potential evil for future generations, it is obvious that a yearly succession of such alien admissions is so grave in its possibilities as to call for immediate inquiry as to its justification, and for drastic correction if unjustified. Even if the intention of the law permitted such discretion to be imposed in any one individual it would be a most unwise and dangerous practice from any point of view.

Immigration Versus Crime

Recent statistics show that in Germany before the war there were only five murders to each million of population; in England less than nine; while in the United States there were 118 to each million of population.

It is alleged that more murders are committed in this country in normal times than in any ten other civilized countries in the world, including Russia. Why? Can our Federal immigration authorities answer this question?

In 1914 the suicide rate in the United States numbered more than 15,000, or .015 of 1 per cent of the entire population. Why? Is it not because the defective and semi-defective offspring of our prohibited classes of admission are too neurotic to stand the strain of the constantly increasing complexity of existence?

To illustrate the relation between immigration and crime it may be stated that between 1890 and 1900—the third lowest decade of immigration in the history of the country—while the population of the State of New York increased 21.2 per cent, the prison population in the same period of time showed a decrease of 6.5 per cent. Witness, however, the complete reversal during the following decade. From 1900 to 1910, the decade of highest immigration in the past ninety-nine years, the population of the State increased 25.4 per cent, while the prison population increased 37.6 per cent. The report of the superintendent of New York State prisons for the year 1910 states that "the increase in our prison population clearly shows that it is due in a large degree to the admission of foreign criminals to the country during the past few years and more than 54 per cent of the increase is chargeable to this direct cause."

Criminal Defectives a Burden

In 1914 alien prisoners constituted 32 per cent of the prison population, while it is exceedingly significant that in 1917, the year of the lowest immigration since 1862, the prison population decreased 537, which is the first decrease shown since the period between 1890 and 1900.

The cost of maintenance of alien prisoners in the State of New York amounts to over a quarter of a million dollars each year; but of exceedingly

greater importance is the cost of the propagation of these criminal strains when released. It is certain that many convicts were defectives at the time of admission and should have been arbitrarily excluded from the country. In many instances aliens have committed crimes within twenty-four hours after their arrival. A noted jurist in referring a deportation recommendation to this department states:

One 17 years of age, recently out of the House of Refuge or City Reformatory, who has been indicted for taking a younger boy on the roof of a tenement house and shooting him in the legs, this day has been committed by me to the Manhattan State Hospital for the Insane. He has been insane or idiotic all of his life.

One 21 years of age, a Greek, arrived in this country about a year and a half ago at the port of New York. Within a month thereafter he was convicted before a city magistrate in New York for vagrancy, and sentenced to three days in the workhouse. He has this day pleaded guilty to attempted grand larceny in the second degree (picking pockets), and he is an undesirable person for this country. The defendant evades a truthful answer to the inquiry upon what ship he arrived.

In 1910 of a total state prison population of 4,610, including Mattewan, there were 1,851 foreign-born inmates. In 1914, of 4,954 total inmates, there were 1,997 foreign-born, and in 1917, of 4,520 total population, including Dannemora, there were 1,811 foreign-born persons.

In the institutions of New York, excluding hospitals for the insane, during the year 1917 there were 13,409 public charges of whom 28.4 per cent were feeble-minded or idiotic, 12.7 per cent epileptics, 20.6 per cent reformatory boys, and 11 per cent reformatory girls.

It is logical to assume that reformatory inmates who are defectives will eventually be set free. Also a large number of the feeble-minded aliens admitted to the country are women of marriageable age. If all those under seventeen or above forty-five years of age are excluded from consideration there remains that most important problem of how to prevent the propagation of these defective classes who remain at large.

Exclusion of Unfit the Only Safeguard

Whatever the intention of the immigration law, in operation, the Bureau of Industries and Immigration, which, under the mandatory provisions of the labor law, is legally responsible for following up the aliens admitted to New York State, so admitted. Discretion in a matter so vital should devolve only upon a commission of medical

and scientific experts whose recommendations no official could override.

It has been estimated that the proportion between the addition to our electorate by attainment of majority, of persons born in this country and those who have been naturalized, indicates that "it is not greater than two to one and possibly closer to one to one," and, owing to the fact that the new stock has been proved to be more prolific than the old, it is clear that the balance of political power will soon be in the hands of the children of foreign-born parents or foreign extraction. All of this argues against the vesting of discretionary power with respect to the admission of unfit and excludable aliens in any single official, instead of in a commission empowered to exclude on purely scientific tests.

Immigration Versus Industry

The United States is harboring a foreign population of 15,000,000 immigrants plus their 19,000,000 children—irrefutable evidence of the

fecundity of the strains introduced through immigration channels and comprising altogether one-third of our total national population. Are they to gravitate into the debit or credit column of the nation? If that prolific blood is tainted, it follows that it will most assuredly become a liability of no mean proportions; but if on the contrary it transmits virility, as a nation we can count the invasion of the immigrant as a huge and ever growing asset.

Among the great surprises of the war was the vast importance of the alien in our army. The total alien registration was 1,243,801, the largest induction being from the State of New York where 239,333 were registered between the ages of 21 and 31, more than 20 per cent of the total registration of the nation. A study of the statistics of deferred classifications would, no doubt, constitute an additional indictment in the category of the unfit. The correspondence between these soldiers and their friends and relatives at home was conducted in forty-three different languages. What a shocking revelation to the theoretic apostles of the "melting-pot." The chief economic value as well as the chief military value of an immigrant must always be his health. The health of a laborer is of no less importance to an industry than the health of a soldier to an army. A physically unfit worker can be only an eventual

The chief economic value as well as the chief military value of an immigrant must always be his health. The health of a laborer is of no less importance to an industry than the health of a soldier to the army. A physically unfit worker can be only an eventual expense to an industry with the result of slackening, lost motion, turnover, and scrapping of materials, all charged to that account.

expense to an industry with the result of slackening, lost motion, turnover, and scrapping of materials, all charged to that account.

In one of our largest mining and reducing industries recently inspected by the writer, an elaborately decorated gymnasium, ball field, tennis court, skating rink, etc., had been constructed under the direction of the so-called "welfare" manager, but the foreign-born laborers were at the same time sleeping in double shifts in vermin infested three-tier bunks, with an allowance of less than 200 cubic feet of air per man, and many were suffering from loathsome and infectious diseases. Healthy men were obliged to occupy not only the same room but the same bunks in the exchange of day and night shifts.

Defectives and Industrial Accidents

In the 60,000 factories of New York, 2,000,000 workers are employed, of whom approximately 1,600,000 are foreign born.

During the year 1915, the first year in which the Workmen's Compensation Law became effective in the State of New York, there were 225,391 reported accidents; in 1916 there were 273,385; in 1917, 313,406; and in 1918, 286,871, costing \$11,500,000, or \$40,000 a day, and representing an average of 274,763 each year—practically as great a number per year in that one state as the entire National Army casualties since we entered the war of which the latest figures announced by the War Department, including prisoners released and returned, amount to 289,416. At the present writing reports of accidents are being received at the rate of 1,000 a day, representing a cost of \$13,000,000 a year as an initial expenditure, to which must be added the cost of medical benefits, administration of the Compensation Law, wages, and cost of turnover, all of which has increased the total direct and indirect cost of accidents in the State of New York to \$35,000,000 yearly, or a rate of about \$117,000 per day for each working day in the year. And 70 per cent of these applicants require the services of an interpreter to present their claims.

In the State of New York, therefore, during the four years between 1914 and 1918 there occurred 1,099,053 industrial accidents—an average of 274,763 each year—a greater number of accident casualties per year in this one state than the entire casualties of the war among the American forces of which the figures at this writing are 273,000. The aftermath of such human havoc will largely produce the same results as follows in the wake of the prohibited classes; we have, therefore, this additional liability to figure in the trial balance of the country. Who can estimate the

total cost? With the productive capacity of a nation reduced, and its dependent and defective classes multiplying in such alarming proportions the tax upon its resources becomes inequitable. In Pennsylvania, the state receiving the second largest quota of immigration, accident casualties are not only voluminous but of the direst nature. During the past year the New York State Industrial Commission has investigated cases involving actions in which the total amount sued for was approximately \$1,500,000. Settlements were obtained amounting to only about \$25,000, in many cases leaving behind derelicts as helpless as any of the survivors of war.

Five years ago, the coming and going, the hiring and firing, of the alien worker was little regarded; Ellis Island could produce many more where he came from. Five years ago the economic aspect of uncompensated accident casualties was considered of small importance. To-day there is forced upon us the consequences of an abnormal war. To-day, the immigrant has become an individual who counts. Moreover, the stoppage in immigration comes at a time when we are facing the greatest industrial crisis and the greatest economic crisis that the world has ever known. Hundreds of thousands of our most efficient workers have been maimed and hundreds of thousands of our alien workers are being withdrawn through industrial accidents that might have been prevented, as well as by re-migration that has but begun. It has been conservatively estimated that upwards of 5,000,000 aliens have declared their intention to return to Europe. These are the common laborers of the Nation. These are the fit and the virile among our immigrants. Our native-born workers will not replace them. The slowing down of our industries under such tremendous loss of manpower is inevitable and we cannot afford to slow down. America for the next century at least should be Europe's workshop. We are the producers for the world. Our very existence depends on our continued driving ahead.

Scrutinize the New Immigrants

Is this tremendous gap to be filled with insane, imbecile, feeble-minded, and syphilitic stock, with the flotsam and jetsam of five years of agony, anarchy, and revolution? The inevitable introduction of severe functional nervous disturbances as well as of an excessive amount of venereal disease through this influx, will tend largely toward an increase of the prohibited classes if the lines are not intensively drawn.

There will be after this war millions of widows and orphans, many of whom will seek a domicile in this country to join relatives and friends.

After five years of agonizing distress and under-nourishment these persons, particularly the children, will be physically and mentally subnormal and the lamentable effects of malnutrition and its congenital sequences cannot but react upon those of more vigorous ages with the result of a weakened maturity. We cannot hope that the renewed immigration will bring in, even among those who cannot be excluded, the hardy stock of bygone years. We are facing a definite weakening of the very fiber upon which our stability as a nation is founded.

Bitter are the casualties of war, but of a bitterness far more intense are the casualties of peace—industrial accidents, preventable disease, carelessness, crime, ignorance, and the violation of Nature's most fundamental laws. The victims of these contingencies create an army of the unfit with nerves as shattered and diseases as incurable as any of those whose sacrifice has been necessarily offered in the service of their country. Some of these evils we must have, but the deliberate and indeed iniquitous introduction of the unfit into the commonwealth is unnecessary and unjust to both our native and foreign born population, and should be forever prevented by the most drastic legislation.

Looking Ahead a Century

"There is no wealth but life," says Ruskin, and if, as some scientists assert, the human race has not improved very much in quality in the last hundred years, it behooves us to take most positive steps to prevent a decided retrogression during the next century; and in as much as the constant depletion in the ranks of the fit but increases the danger of multiplying the unfit, we have in the next few years just about double the danger to face with half the resources with which to combat it.

Should these present-day conditions continue, one can predict very accurately what will happen in the future. When a people or a race is lowered in its efficiency, the apex of its grandeur has been reached. History but repeats itself in this as in other events. Greece, Rome, and Egypt

can credit their decline and downfall to a lowering of the quality of their men. Whether we as a nation can bring any radical changes about in our generation is problematical. We may reap a harvest that no governmental action will be able to control if these conditions are permitted to continue.

The State of New York has room for other millions of mentally and physically sound immigrants, whom it can well afford to protect and educate from an economic point of view. The financial resources of the government for such development and education should, however, not be curtailed by an unnecessary and finally useless expenditure for maintenance of those who are unfit and who multiply their unfit progeny in such alarming proportions.

These conditions must be squarely met. They are not theories but well authenticated facts. They cannot be ignored. They brush aside all political considerations and become one of the most vital issues of the day.

John Bright denounced the policy of the empire that would bring misery to the nation when he said: "I believe that there is no permanent greatness in a nation unless it is based on morality. I care for the condition of the people among whom I live. * * * The moral law was not written for men alone in their individual character, but it was written as well for nations, and for nations great as this of which we are citizens. If nations reject and deride that moral law there is a penalty which will inevitably follow. It may not come at once, it may not come in our lifetime, but, rely upon it, the great Italian is not a poet only, but a prophet when he says:

"The sword of heaven is not in haste to smite,
Nor yet doth linger."

Typhoid Vaccination

"Although the protective value of antityphoid vaccination is no longer open to question, the practice of this procedure should under no circumstances be regarded as a substitute for the observance of sanitary precautions," warns the United States Public Health Service in the *Public Health Report* of March 28, 1919, in reproducing the circular by the Chief Surgeon of the American Expeditionary Forces on "Typhoid and Paratyphoid Fevers."

LOWERING THE NATION'S EFFICIENCY

Should these present day conditions continue, one can predict very accurately what will happen in the future. When a race is lowered in its efficiency, the apex of its grandeur has been reached. History but repeats itself in this as in other events. Greece, Rome, and Egypt can credit their decline and downfall to a lowering of the quality of their men. Whether we as a nation can bring any radical changes about in our generation is problematical. We may reap a harvest that no governmental action will be able to control if these conditions are permitted to continue.

TENT RESTORES HEALTH AND HOME

A tent pitched on the roof of a New York City dwelling became the home hospital for the husband and wife who are enjoying the sunlight and fresh air in the accompanying illustration. Both were suffering from pulmonary tuberculosis. A summer spent under the canvas and in the sunlight worked a miracle, and helped to restore parents and children to independence. The family was found at Christmas, 1907, without money or food. The three children—the eldest only 11—were placed out to board, and a boarding place was found for the two patients where a tent might be pitched on a flat roof. Treatment was taken and both patients recovered.

The family is now re-united. The woman has been doing her own house-work for eight years, and her husband, who is now a motorman, has been self-supporting for the same length of time.

The patients found much to encourage them at the start when they began to put on weight and regain sufficient strength to return to work, all of which helped their recovery.

AFRICA COMPLETES INFLUENZA SURVEY

The influenza epidemic was extraordinarily severe in the Union of South Africa. The true severity of the epidemic is indicated by an incidence rate of nearly one in every two persons, as reported by the Influenza Epidemic Commission appointed by the Governor General. The average incidence rate was found to be 42.79 per cent.

Among the non-European peoples the disease was more prevalent and resulted in more fatalities in proportion to the number of cases, than among European residents of the Union. The non-European group is shown to have an incidence rate of 46.03 per cent, with a fatality of 5.90 per cent of the persons attacked. Compared to these figures, the Europeans had an incidence rate of 32.06 per cent, with a fatality of 2.57 per cent.

There were 139,471 deaths in about four months. In the non-European group, a total of 127,745 deaths occurred among 4,679,152 persons, or 27.19 per 1,000 of the population. The European group shows 11,726 deaths among a total of 1,418,060 persons or 8.26 per 1,000.

The deaths were most numerous in the age groups of the third and fourth decades, and likewise the occurrence of the disease was most frequent in these groups. Fatalities were numerous among pregnant women. The locality reporting the highest death rate is Cape Province, where there were 33.5 deaths per 1,000 of population. The Commission notes that the Province of Natal had the lowest death rate of any province of the Union, the proportion being about one-third that of Cape Province. A coincidence is observed in the fact that during an epidemic of influenza in 1889-90, as in the present epidemic,

Natal, and more particularly the city of Durban, suffered less than other parts of the country. It is shown that European immigrants suffered less than persons of European parentage who were born in Africa.

"Home hospital" improvised on a flat roof. The patients, husband and wife, were both ill with pulmonary tuberculosis and unable to work. Both have recovered and have been working for eight years.

The Commission suggests that the reasons for the higher incidence and mortality rates among the native or non-European group of the population may be found in the well recognized susceptibility of the native and colored population to diseases of the respiratory tract, poor housing conditions, a lack of even the most rudimentary knowledge of how to care for the sick, and prejudice against hospitals and medical treatment. To combat these conditions, the local authorities in all provinces were given the power to compulsorily remove to a hospital or other place of isolation, either the persons suffering or suspected to be suffering from the disease, or those who had been exposed to infection.

The following recommendations on sanitary measures which the government is advised to take as a safeguard against any similar outbreak of disease, are contained in the report of the Commission:

"There is no evidence before the Commission that the virulence of the disease had any definite correlation with poor sanitary conditions, but nevertheless, it is clear that bad housing, congestion, and insanitary conditions facilitated the spread of the disease, and tended to increase mortality."

"The Commission desires strongly to emphasize the necessity of devoting immediate attention to the improvement of housing and sanitary conditions in slum areas and in native locations."

Uncle Sam Issues Health Leaflets

The *Health Leaflets* which have been prepared by the United States Public Health Service for popular distribution are superior to many similar bulletins, in their brevity and ease of reading. The first of the leaflets, No. 1 of the *Keep Well Series*, bears the title, "The Road to Health." Diphtheria and tuberculosis are subjects of other leaflets recently issued. They may be obtained upon request to the Public Health Service, Washington, D. C.

COORDINATION OF HEALTH AND SOCIAL AGENCIES

BY GEORGE THOMAS PALMER, M.D., PRESIDENT OF THE ILLINOIS TUBERCULOSIS ASSOCIATION; ASSISTANT DIRECTOR OF THE ILLINOIS STATE DEPARTMENT OF PUBLIC HEALTH, SPRINGFIELD, ILLINOIS

I. Introductory

PARTICIPATION in the world war gave to the American people a new social conscience, taught them a new standard of generosity, and impressed upon them for the first time the practical value of individual and community health. The patriotic spirit of the war, and particularly the personal interest created through the sons of over three million families participating in it, enlisted in war work hundreds of thousands of men and women who had never engaged in any kind of public service before and whose experiences have made them not only ready, but keen for further social activity. The sudden signing of the armistice left thousands of idle but willing hands associated with a number of organizations which had attained great power and momentum. This vast army of men and women are ready to engage in medical and social work, and in their spirit of enthusiasm, they want and expect to see definite action and speedy development.

The Awakening Social Conscience

In the comparative apathy which existed before the war, health and social agencies were hampered and retarded by the magnitude of their problems and by inability adequately to finance them. The war has given us a broader vision and a new conception of generosity. Philanthropists who formerly talked in terms of hundreds now act in terms of thousands of dollars and the rank and file of the people, who formerly contributed nothing toward social or community progress, have come to feel that they have a financial responsibility which they are not disposed to shirk.

Thus we find ourselves with a new army of lay workers, fired with an enthusiasm born of their first adventures in public service and with financial resources available such as we have never known before. Many of these new recruits are business men of large affairs who have previously

Dr. Palmer in his official capacity as an administrative health officer, and by his past experience, is well fitted to write authoritatively on public health problems. In 1901 as head of the Trinity Diet of Infants of Chicago, he was one of the pioneers in child welfare work in the Middle West. Later he was assistant secretary of the Illinois State Board of Health, in charge of communicable diseases. Then in the capacity of health officer of Springfield he carried out the most complete sanitary survey made of any city up to that time, the results of his housing investigations being still widely quoted.

been engrossed in their own enterprises and they are naturally disposed to apply so-called "business principles" to health and social problems, confident that business system, backed by adequate funds, will be as productive in the solution of health and social problems as in the commercial world. Consequently they are advocating combination, consolidation, the elimination of lost motion and over-lapping, the centralization of power, and other factors which have made for economy and efficiency in industry. These great potential forces, now that the war is over, are naturally looking for the most important field of activity and our experiences during the war have indicated that such a field is to be found in the promotion of individual and community health.

Health the Paramount Problem

The disclosures of the exemption boards and of the army medical examiners came as a distinct shock to the American people. The wide prevalence of physical inefficiency among our young men, and particularly the previously unsuspected magnitude of our tuberculosis and venereal disease problems, were a blow to our national egotism. Hard-headed men had it impressed upon them for the first time that the strength of a nation is no greater than that of the people who constitute it.

In addition to the revelations as to American health by examining boards, the influenza epidemic of last autumn gave a tremendous impetus to national public health work. Just at the time of greatest urgency, the mobilization of troops was suspended and essential industrial activity was slowed down on account of the epidemic and for several days it appeared quite possible that, in spite of our tremendous wealth in money and our strength in men, our participation in the

world war might end in failure purely on account of preventable diseases. For the first time in the history of the nation, public health assumed the place to which it is justly entitled—the nation's problem of paramount importance.

A Quickened Public Spirit

Awakened by our own tragic experiences, the American people have come to view with greater interest the health problems of the European nations. We have seen France and Belgium attempting to solve the tremendously important question of repopulation to replace the thousands of young men lost by war and to prepare for the gigantic undertaking of reconstruction. We have seen the child assume a place of new importance and have come to recognize for the first time that child conservation is a subject worthy of profound consideration by our statesmen, business men, and men of affairs. Public health and individual health have loomed out of the background of war, the most worthy field for the interest and activity of the public spirited people of the nation.

II.

As has been frequently pointed out, there have been developed in the United States, within the past quarter of a century, a very large number of volunteer agencies engaged more or less actively in some form of public health endeavor. For the most part these agencies have addressed themselves to individual, specialized problems, ignoring in a large measure the other and closely associated health activities except as they touched immediately upon their own organizations. In many instances these extra-governmental agencies were more liberally financed and more capable of developing largely specialized organizations than the duly constituted governmental health authorities, and, for that reason, they have been responsible for a very large part of the gratifying progress in public health work that has been made in the United States during the past decade. Broad-minded public health officials have been ready to recognize this service and have utilized its results to the tremendous advantage of the people.

Properly Financed Movements Succeed

This sharply defined division of the several fields of public health endeavor has been open to serious objection. It has been responsible for a very real over-lapping and it has unquestionably led to the placing of undue accent on certain phases of health work as compared with the stress laid upon phases equally, or more, important. The independent and uncoordinated activities of these numerous organizations have unques-

tionably been responsible for a maximum of expense and a decided loss of efficiency.

On the other hand, the narrow specialization to which objection is now made has resulted in compelling recognition for a number of important branches of public health work. Tuberculosis was notoriously ignored by public health authorities from time immemorial until a specialized organization, adequately financed, demanded recognition for this wide-spread and destructive disease; while child welfare work, housing, the prevention of blindness and other important subjects had shared a similar experience. It is very doubtful if many of the governmental health agencies would have accorded the consideration to these subjects they now have had if not been for the inconsistency with which these specialized organizations demanded recognition and even over-recognition for their individual lines of work.

Consequently it appears that strict specialization by extra-governmental agencies in the past has not been a serious mistake and that the results have justified the policy regardless of its extravagance as measured by our present standards of economy and efficiency. If consolidation and coordination are desirable, as they appear to be, the time for such consolidation has but recently arrived. In this connection there has been no unfortunate delay.

The feature in the programs of extra-governmental agencies in the past which has been most open to criticism is that their point of view has been too narrow. Engrossed in their own specialties, they failed to recognize that their own progress would be accelerated by a broader knowledge of those phases of health and social work closely related to them.

Facts That Are Overlooked

Those engaged in the tuberculosis movement, which constitutes the best organized and most liberally financed of extra-governmental health agencies in the nation, have unquestionably devoted themselves assiduously to a warfare against the tubercle bacillus without recognizing that many other factors are contributing to the steadily decreasing tuberculosis mortality and morbidity. They have prided themselves that the death rate from tuberculosis has decreased about 30 per cent in the last quarter of a century, during which their propaganda have been active, while overlooking the fact that the death rate was rapidly decreasing during the previous twenty-five years and prior to the development of tuberculosis societies. When the tuberculosis enthusiast has investigated the milk supply, he has usually done so with his mind centered upon bovine tuberculosis or the accidental tuberculous contam-

ination of milk, without sufficient regard to the influence of a good milk supply in the betterment of general health with consequent decreased incidence of tuberculous disease. When his studies have taken him into the field of housing, the tuberculosis worker has devoted himself largely to the viability of the tubercle bacillus in dark and unventilated rooms with the possibility of conveyance of infection from the previous tenant to his successor, failing to give sufficient thought to the general consideration of light, ventilation, overcrowding, and the various phases of housing which affect individual and community health and strength.

There have been times when tuberculosis workers have questioned the wisdom of the expenditure of their funds in carrying out child welfare work and other broad, general health activities, without realizing that, as now seems apparent, such general activities are quite as responsible for the rapidly decreasing tuberculosis death rate as the narrower combat against the tubercle bacillus and specific infection.

Health Workers on Common Ground

Incidentally, regardless of this rather narrow point of view, tuberculosis organizations have actually done more than any other agencies in bringing together medical and social forces which have always been too far divorced in the meeting of public health problems. In certain vast areas of the nation, practically all of the dispensaries, the visiting nurse service, child welfare work, and extra-governmental public health activities have been financed through Red Cross Christmas Seals and the national or state tuberculosis associations, so that their work has been broader and wiser than their expressed policies and the theories of the average tuberculosis propagandist.

With like truth it may be stated that public health officials and many volunteer health workers, whose interests necessarily touch at many angles upon the tuberculosis problem, have attempted to operate without an intelligent conception of the fundamental facts of tuberculosis work. In times past, at any rate, local and state health authorities have attempted to deal with tuberculosis purely as a contagious or infectious disease, much as they do with scarlet fever or diphtheria, without recognizing the tremendous social factors involved or the fact that if every person with tuberculosis infection were isolated or quarantined, there would not be more than 20 per cent of the adult population free to engage in the affairs of the world.

Professional charity workers have pursued the calm and even tenor of their ways, generally

ignorant of the fundamental facts concerning that disease which must be recognized as producing more destitution and poverty than all other diseases combined and to which the poverty-stricken and under-nourished are peculiarly susceptible. The niggardly relief afforded by charity agencies to tuberculous persons, in the belief that this class of individuals may be regarded as merely among the "sick poor" is one of the serious faults in our professional relief organizations and one which has already spelled failure and defeat of purpose. On the other hand, the lack of knowledge of the principles of outdoor relief on the part of tuberculosis workers has also stood in the way of a clear understanding between tuberculosis and charity agencies.

Shortcomings of Welfare Agencies

The instances of failure to produce the maximum of results through this lack of understanding of fundamental principles among workers in closely allied health and social activities, may be enumerated in large numbers, thus arguing that there must be a central agency or a point of contact where a broader viewpoint may be obtained for all. The attempts to attain this end through conferences or organizations representing all phases of medical and social work have resulted in failure, partly because these conferences have been divided into specialized groups in which enthusiasts gather with their own fellows, paying little or no attention to the deliberations of the other sections. This condition of lack of understanding is not deliberate. The average enthusiastic medical or social specialist does not realize that he cannot know the essential facts of his own specialty until he has gained an infinitely broader conception of the fundamental facts of allied specialties.

How the Failures Come About

Another objection to extra-governmental medical and social work, as it has been carried out in the past, is that there is serious over-lapping which results not only in financial waste, but often in the actual nullification of the good accomplished by all of the several competing agencies. This is perhaps best illustrated in the programs of tuberculosis, child welfare, and parent-teacher associations. If we accept, as we must, the modern doctrine that tuberculosis is almost invariably a matter of childhood infection, that women are particularly susceptible to the activation of tuberculous disease at the time of childbirth, and that the time for effective prevention of tuberculous disease is during childhood and youth, then it must be that a successful campaign against tuberculosis would involve prenatal and postnatal care

of mothers, the supervision of infancy, the control of milk supply, medical and nursing school supervision, school sanitation, open air schools, or other provision for underdeveloped children, and the general development of robust and healthful infancy and childhood. Organized child welfare associations, to attain their desired ends, must follow a similar program, while parent-teacher associations, so far as they interest themselves in matters of health, must subscribe to at least a part of such a program; and yet, in a large measure, these three extra-governmental organizations conduct their activities without serious regard for the aims and purposes of each other, and, at times, even enter into active competition as to which shall have the opportunity and credit for this essential work.

The Ill Results of Bad Methods

The spectacle of general visiting nurses entering into wordy, if notistic, combat with child welfare nurses and tuberculosis nurses for the possession of some one, destitute family is quite as convincing of the unfortunate over-lapping of medical and nursing agencies as was the possession of seven turkeys on a single Thanksgiving day by a family that ordinarily went without sufficient food, all on account of the misdirected and misguided philanthropic effort in a certain community.

At the present time, infinite confusion is being experienced in the public health nursing of rural communities on account of the well meant and enthusiastic activities of a number of agencies, each desiring to be useful as the sponsor for this important part of public health administration.

III.

Other adequate reasons for coordination have been suggested from time to time, but argument on the subject seems no longer necessary. The case is clearly proved. Money is wasted in useless over-lapping of work and possibly in the employment of executive forces which outweigh the actual workers; and, to add to the seriousness of this point, it is recognized that far too much of the time and money of the extra-governmental agencies are expended in raising funds for their support.

Coordination, when it comes, however, must be wisely planned so that the individuality of the more important extra-governmental agencies shall not be lost and, particularly, that the advantage of specialization on the part of men and women now enthusiastic in their individual lines shall not be sacrificed. The all-around, all-comprehending physician is a rare personage, and the health officer or public official capable of the mas-

tery of all phases of public health and social endeavor has not yet appeared in this or any other country. In the present state of our development, the loss of this specialization would outweigh the advantages to be gained by any form of coordination or combination.

How to Gain Coordination

With the firm hold which the idea of coordinating health and social agencies has taken upon the American people, several plans have been rather indefinitely suggested, and several agencies have been mentioned as the central or coordinating forces.

The attempts at mutual understanding and the loose cooperation in the form of conferences has proved and will continue to prove ineffective. To bring about the desired ends of economy and efficiency through a closer understanding between the various agencies, the meeting point must be stable and the relationship definite and it is very doubtful if any existing extra-governmental agency is sufficiently strong or prominent that it would be generally acceptable to all of the specialized agencies for any form of strong leadership. Extra-governmental agencies are essentially temporary in character. As a rule, their destinies are guided by very small groups of individuals whose death or removal would materially affect the strength and future of their organizations. The history of the rise and fall of ambitious organizations in the past is sufficient proof of this assertion.

It has been stated that national, extra-governmental agencies dealing more or less directly with health have an annual budget of approximately \$1,500,000, while the National Tuberculosis Association passed through its treasury during the present year the sum of \$2,500,000, an amount which gives promise of increasing with succeeding years. It is clear that these agencies, aside from the importance of their health work, control sums of money, now being more or less wisely expended, which cannot be tampered with except after serious consideration and it is not reasonable to assume that an organization which has developed a strong staff and large resources would be willing to yield itself to a definite coordination under a leadership less firmly established, less liberally capitalized, or less stable in its existence.

IV.

For this reason, it appears clear that the central rallying ground or point of contact, which now seems to be insistently demanded, shall be a governmental agency, duly and permanently established by law, and this idea seems the more

rational when we consider the fundamental principle which underlies all extra-governmental health work. For many years it has been held that public health and social work is a proper and natural charge upon the tax-paying public and that extra-governmental agencies are developed largely for educational purposes with the idea that, when they have demonstrated their usefulness, their activities shall be passed over to governmental organizations.

Personnel of Advisory Body

In the various states, it seems a practicable plan that the presidents or executive officers of all the state-wide, extra-governmental health and social agencies should constitute an active advisory council for the State Department of Public Health, the state health officer, regardless of the personality of that individual, becoming chairman and presiding over the deliberations of such an organization. Likewise it seems practicable for the national health and welfare associations to form a similar association with the United States Public Health Service.

It is not desirable, in such a plan, that the extra-governmental organizations should surrender any of their individuality or become subservient in any way to the state health authorities. In fact, even casual consideration of the program will indicate that, instead of losing strength, these coordinated organizations, representing a very large percentage of the intelligent population of the state, would be instrumental in stimulating the state health department to better and more efficient activity and this would be the more certain if, as seems desirable, there should be added to this advisory council the presidents or executive officers of the state federation of labor, the state press association, the state manufacturers' association, the state organization of chambers of commerce, the state federation of women's clubs, and similar bodies whose connection is indirect, but whose interest is manifestly great in the promotion of health and the prevention of disease.

How Issues Would Be Settled

Such a council should meet regularly and with relative frequency. The state health officer would be in position to indicate to what extent the state or the duly constituted authorities of local communities are prepared to take over any part of the activities of any of the extra-governmental agencies, thereby releasing the funds of these organizations for the extension of other important work in which the public agencies are not prepared to engage.

In questions of serious over-lapping, or in

equally serious questions of important health activities neglected by the various agencies, the state health officer would, as a rule, constitute an unbiased and impartial mediator, assigning special phases of work to the organization best fitted to carry it out as his judgment might indicate. Such decisions would not be binding and from them an appeal could be taken to the majority opinion of the council as a whole, all of whose members would have at least a reasonably intelligent conception of the fitness of the presiding officer's decision.

Aside from the fact that such a representative council would stimulate the state health department to greater endeavor and would serve as a check upon those officials inclined to shirk their responsibilities, there is no question but that they would bring to the department not only technical guidance of a specialized character, but also information as to the need for general health activities in the several sections of the state. On the other hand, the recognition of the extra-governmental agency by this official branch of the state government could not but strengthen the organization and give it more or less recognized standing in the commonwealth, depending upon the popularity and strength of the health officials of that particular state, while the close association with governmental agencies would permit the utilization, to a certain extent at least, of the legal power and authority possessed by the state, but denied to volunteer agencies, yet which is essential in bringing about lasting reform.

Where Difficulties Might Exist

Objection to this plan may present itself on the ground that in some of the states the public health departments are so weak, so inefficient, or so politics-ridden as to be unfitted for this large measure of leadership. It is possibly true that in some states there exist single, extra-governmental organizations better financed and quite as influential as the official health department. If this is true, the paramount need of that state is the development of sentiment looking toward a strong official health organization and the coordinated extra-governmental agencies should be engaged in nothing more important than this project.

The further objection that certain state health officials are notoriously antagonistic to extra-governmental agencies, is not an argument against this plan, but rather one distinctly in its favor. The public health worker who will brook no suggestion or interference on the part of the people in what is essentially the people's business, is sorely in need of the disciplinary effect which the

wide dissemination of the knowledge of his narrow attitude would in most cases bring about.

V.

The United States Public Health Service maintains toward the health departments of the several states very much the same relationship that the volunteer national health organizations maintain toward their state representatives. Fortunately or unfortunately, in the creation of the Federal government, the states retained to themselves the supervision and control of public health matters and, consequently, the United States Public Health Service assumes a relationship with state health departments which is advisory and helpful rather than mandatory or dictatorial.

Since the policies of this relationship have been reasonably modified, the contact between the Federal health authorities and those of the several states has become close and exceedingly helpful, the conferences of state and provincial health authorities with the Surgeon General of the Health Service bringing about coordinated action which is becoming more and more satisfactory to all parties concerned.

It seems thoroughly practicable that a conference of national volunteer associations, including commercial, civic, industrial, and other agencies vitally interested in health, might organize itself, with the United States Public Health Service as its rallying ground, and the Surgeon General of the Public Health Service as its permanent, presiding officer and that, through such an arrangement, there could be established as satisfying co-ordination as could be produced in the individual states in accordance with the plan that has just been described.

State organizations, as a rule, are active and executive in character, reaching, at least indirectly, the communities and the people. National health agencies, as a rule, are advisory in character and devote themselves largely to the development of organization. Within the state, it is vitally important that the extra-governmental health and social agencies shall be coordinated, but it is just as essential that the national bodies, in their advisory capacity and in guiding the general courses of work within the states, shall have just as close cooperation and just as clear an understanding of the points of contact between themselves and other bodies engaged in carrying out similar or related programs.

Out of the observance of Health Promotion Week in Illinois, set aside by the General Assembly for the bringing together of health and social and allied agencies to prepare for reconstruction work, there has developed an advisory council in Illinois created along the lines indicated in these

pages. While it is yet too early to determine or even to speculate intelligently upon the outcome of this experiment, it may be said that on the part of all of the organizations party to it, there is a reasonable hope that it may be the means, though subject to repeated and radical changes, for the solution of the most serious administrative problem in the development of our social and public health activities.

SCHOOL HEAD URGES HEALTH STUDY

Reading, writing, arithmetic, and health were pronounced the essential studies for American boys and girls by Charles E. Chadsey, superintendent of schools of Chicago, in an address before the American Physical Education Association during April, at the twenty-third convention of the association, held in Chicago.

Both Dr. Chadsey and Professor Charles H. Judd, director of the College of Education of Chicago University, appealed to the members of the Physical Education Association to work out a standardized program in the science of health that will enable cities and states to introduce it as a required study in the schools.

"I want to charge the physical director with the responsibility of devising a method, which, when put in practice, will give the physical instructor exact knowledge of the actual physical condition of each individual child under his supervision at all times," said Dr. Chadsey in defining his ideal and its purpose. "Then I want him to do for each pupil who is below normal that which will make him a normal individual."

He expressed the hope that before long physical education and health instruction will be given a place in the educational system that will make health a subject of coordinate importance with the studies which have intellectual training as their object.

Professor Judd termed the study of health a "science of personal fitness." He asked the association to "intellectualize" physical education—to think less about arm movements and more about the application of health rules, hygiene, exercise, and corrective or preventive teaching in personal living. Psychology, he said, should be linked with physiology.

Major General Leonard Wood, commanding the Central Department of the United States army, described the results of corrective, remedial methods which the army adopted to reclaim its unfit men.

The remedial or development battalions corrected or improved the physical deficiency of every man sent to them for treatment, he declared. He defined the policy of the army as that of betterment for every soldier.

Dr. Thomas A. Storey, secretary of the Interdepartment Social Hygiene Board at Washington, and vice president of the National Council of the Physical Education Association, outlined a program of national and state health legislation looking toward the achievement of the goal marked off by General Wood, Superintendent Chadsey, and Professor Judd.

William Burdick, M.D., president of the National Council of the association, reviewed the activities of the association and its members during the period of the war.

J. H. McCurdy, M.D., physical director of the Y.M.C.A. with the American Expeditionary Forces, and secretary-treasurer of the Physical Education Association, told of his work abroad.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., Editor

REHABILITATION OF DISABLED SOLDIERS

THE war has taught many lessons in the conservation of man power but none which has had more profound effect than the program instituted for the physical and vocational rehabilitation of wounded men. In other wars the disabled men have returned to their home communities, perhaps after having been granted pensions, and have been allowed to live out their lives as objects of charity. There has been a general feeling that when a soldier has offered his life for his country, and has been disabled, the country owes him a livelihood without any further effort on his part. Such a course has been disastrous to the men themselves because of the effect it has had upon their morale. It is not kindness to a man to make him dependent and to allow him to feel his dependency. Few active men desire to remain helpless even though they may have their direct physical wants cared for. There is a divine discontent possessed by most people which encourages them to increase their earning capacity. Dependence breeds dependence and when a man has become confirmed in it he is not only satisfied with it, but constantly increases his demands for assistance. This is true whether a man has the glory of the fighting man to sustain him or whether he has no legitimate claim for increasing charity.

At the beginning of the war the Federal government took the first steps in the plan for rehabilitating soldiers by providing the war risk insurance plan which scientifically distributed the losses from disabilities of war service. Instead of relying upon payment of pensions the government instituted insurance for which the men paid the larger part, but to which the government contributed. Under this plan the men were entitled

to payments according to the disability sustained and for medical service after their discharge from the army during their periods of disability. It is not a gift; it is a plain business proposition. Insurance principles were applied and so far as the men were concerned it was no different than if they had applied for casualty insurance in a private company, except that the extra hazards of war were borne by the government.

The next step was the organization of the physical reconstruction service of the Surgeon General's department wherein it was provided that complete restorative treatment should be given before the men were discharged from the army. Business principles combined here with humanity, to establish the idea of restorative treatment. Since the Bureau of War Risk Insurance must pay throughout the period of disability, it becomes clear that the best type of medical service must be instituted so that the disability should be as limited as possible.

Fortunately, the idea was more clearly seen than it has been in the case of workmen's compensation insurance for industrial accidents. When men were discharged from the army, they were turned over to the Bureau of War Risk Insurance, which paid them for the disability in proportion to its severity. Here again it was recognized that medical service would save dollars in the prevention of increased and prolonged disability. Medical service has, therefore, been instituted to serve disabled men after their discharge from the army.

But another step was needed to complete the process of rehabilitation. A man might be partially restored physically, but be unable to carry on any gainful employment or be incapacitated from carrying on the work of the vocation in which he had been schooled before being injured. A man whose trade depends upon his right arm

would be helpless if that arm were gone. Men whose work depends upon keen eyesight would be prevented from carrying on their work by even slight impairment of vision. The loss of a man's trade through disability is a serious blow to his independence. Unless he can be restored to effective working power he is pretty likely to deteriorate and become a charge upon the insurance system.

Early in the war Congress passed the vocational rehabilitation act and placed upon the Federal Board for Vocational Education the duty of studying the problem and developing courses to meet the needs of disabled men. Under the plan a nation-wide vocational training service has been established. Several thousand cases have already been examined, and hundreds of soldiers are receiving training in many types of skilled and semi-skilled trades and in the professions as well. When a soldier or sailor has been released from the service and is entitled to receive compensation for injury from the war risk bureau, he is entitled to receive vocational training under the direction of the Federal Board. It is not compulsory, but every inducement is held before him to take the training. Efforts are made to reach men directly, and also through their families and friends before they develop habits which tend to incapacitate them for further effort.

The object of the physical restoration and vocational training as developed by the Surgeon-General's office, the Bureau of War Risk Insurance, and the Federal Board of Vocational Education has been to inspire men with the idea that disability does not mean dependency, and that there is a chance for each man to be an effective worker in spite of such handicap. As soon, therefore, as possible the restorative stimulus of hope is applied and men are given a new heart to look forward to an active part in the nation's work. The whole system is a high tribute to the vision of those who saw that the conservation of man power is one of the vital needs of the nation.

MOTHERHOOD AND CHILD WELFARE

ONE of the notable, truly significant prece-
dents that the reconstruction period is bring-
ing about is the phenomena of two great social
forces of widely separate origin, coming together
to form a junction. The one is an outgrowth of
medical science having its inception and growth
in service to humanity; the other is a popular
movement carried on by propaganda.

The first is the knowledge, help, and profes-
sional service of the physician in organized ma-
ternity care and protection for mothers. The

legislation that has been enacted in the states of this country and in other countries for the protection of mothers, and the service rendered by city health departments and other agencies for the care and protection of pregnant mothers, has made an organized work of that which was formerly an individual matter between an individual physician and his patient. A work thus organized and vested with statutory power becomes a force in the social life of communities.

The second great force, which developed from another source and now joins itself to the first, is the child welfare movement. It has created standards for the protection of the child and has embodied these standards in the statutes.

Between the child welfare movement and maternity medical and nursing service, including prenatal care for mothers, there is apparent a practicable and applicable unity of purpose. Those who enjoy the privilege of leadership control in the work of child welfare agencies see clearly the advantage of a junction of the two activities.

The public school was the first point of contact in organizing the work of child welfare. Whatever success has attended the movement has come by the slow and difficult process of forming many successive points of contact with children and parents. One of the points of contact is the public playground. Another is the medical examination in schools. Experience has shown that a starting point earlier in the life of the child than the age at which he enters school must be established. Those who are alive to the vital problems that affect the health of the child in the pre-school period know that many of the handicaps with which they have been dealing might have been prevented if they could have reached the child earlier in life. They know that if the young child can be safeguarded against preventable physical ills and defects, their problems will be largely solved. Realizing this, they are seeking a starting point in the home, while the child is an infant. They are turning their attention to maternity care and nursing service for mothers.

England made an advance in this direction during the war by extending the facilities for maternity medical and nursing service within reach of every family, as a war measure, its purpose being to repopulate the nation and replace the losses of life in war. The present-day problem is in educating mothers to the use of these facilities. The Local Government Board has set a standard for the entire land. According to Sir Arthur News-holme, chief medical officer of the Board, the time is coming when every home in which there is a child born will have access to the service and guidance thus provided.

OCCUPATIONAL THERAPY IN CIVILIAN HOSPITALS

BY G. CANBY ROBINSON, M.D., ASSOCIATE PROFESSOR OF MEDICINE, WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, ST. LOUIS, MISSOURI*

THE lessons of the war, which have been learned in the cruellest school of experience of all time, must be translated into civilian use for future generations. This is the paramount duty of the present, to which all efforts must be bent at this time for years to come. The new outlook for the physically handicapped is one of these great lessons, and every one should strive with determination to make the most of it for future humanity. The adoption to civilian life of the methods for the conservation of man-power which have been so important during the war is one of the problems of the hour.

The Workshops in Hospitals

This thought has taken hold of many people in our community, St. Louis, Missouri, and there the problem of the physically handicapped is being attacked from several points of view. A group of people have come together, representing the Council of National Defense, the public schools, the two University medical schools, the medical institutions conducted by the city, the St. Louis School of Fine Arts of Washington University, the ninth district of the Federal Board for Vocational Education, the Rankin Trade School, and the Junior League, as well as business and financial interests. This group has established ward occupations and curative workshops in the City Hospital of eight hundred beds, in the City Sanitarium, which cares for twenty-five hundred insane patients, and in the St. Louis Children's and the Barnes hospitals, both affiliated with the Washington University Medical School. It is making efforts to introduce occupational therapy through the Red Cross into the hospital of the Public Health Service and through the St. Louis Tuberculosis Society into the city institution for the care of tuberculosis patients. A school has been established for the training of teachers of

THE CURATIVE POWER OF WORK

Occupational therapy is a curative agent which should be at the disposal of every member of a hospital staff.

Occupational therapy should be available in private practice and should be carried to the homes of the well-to-do.

There should be trained teachers serving as private practitioners to carry out the doctor's orders of prescribed work.

The impetus given to work as a curative agent by the war will, it is hoped, continue and increase for the benefit of future generations.

occupations in which the School of Fine Arts of Washington University and the various hospitals have cooperated.

Two of the hospitals in which occupational therapy is being conducted, are used extensively for medical teaching, and as the medical students are seeing and assisting in the work, it is to be confidently expected that in time they will become doctors who will have a knowledge of and interest in occupa-

tional therapy. This we consider an important point in its development.

There has, also, been established a placement bureau for the physically handicapped, under the auspices of the Red Cross, which has undertaken the industrial placement of patients from the workshops and from any other source and has co-operated in other parts of the work.

Work as a Curative Agent

The organization and incorporation of the St. Louis Association for the Promotion of Occupational Therapy is underway. This Association has for its objects the training of teachers of occupational therapy, the conducting and extending the use of occupations as a curative measure, and the undertaking of anything which may improve the industrial and economic conditions of the physically and mentally handicapped. It is the hope of the association that it may eventually establish various activities which will bridge the chasm which now exists between the hospital world and the industrial world—the chasm into which so many have to look when leaving the hospitals and the passage of which is fraught with so much danger and depression.

The first curative workshop established in St. Louis has been in successful operation for more than two years. It has been established in connection with the dispensary and affiliated hospitals of the Washington University School of Medicine. It has been financed by the Junior League of St. Louis, and is conducted by a committee com-

*This paper was read before the International Conference for the Disabled, New York City, March 16-23, 1919.

posed of equal numbers of the medical staff and social service department of the Medical School and of the Junior League. Weaving, cement work, toy making, woodwork, and sewing have been carried on. A variety of patients have worked in the shop, most of whom have come from the large general dispensary, conducted by the medical school.

The men and women, old and young, who have worked in the shop have presented various types of illness and disability. Functional and organic nervous disorders, heart disease, nephritis, exophthalmic goitre, resected joints, chronic arthritis, and a variety of surgical conditions represent the majority of the cases. Because of this variety, many problems have been presented, and frequently hydrotherapy, massage, and medical treatment have been carried on simultaneously with occupational therapy.

The Types of Problems

The writer has had an opportunity to follow closely the therapeutic value of occupations in these cases and has endeavored to form an opinion as to its merits from the point of view of the physician interested primarily in the treatment of the type of cases commonly met with in civilian practice.

Toy making has curative value in the recovery of these girls, who are suffering from nervous ailments.

tice. In order to show the basis for the opinion which has been formed, a brief account of what has been accomplished in a few cases illustrating different types of problems will be given.

A rather frail looking man of thirty-one years entered the dispensary with the statement that he had heart disease, and had not been able to carry on his work as a paper hanger for fifteen months, during which time he had been practically idle except, as his history revealed, for his constant thoughts about himself. He was thoroughly discouraged and disheartened. Although his symptoms were such as could be accounted for by heart disease, a searching examination failed to show any evidence of a cardiac disorder. A statement of the facts did not convince the patient, so he was sent into the shop to be shown what he could do. He soon became interested and encouraged, and after several months during which time he became an excellent wood worker, he was ready to go back to outside work. He became one of the greatest assets of the shop by encouraging the newcomer, and by setting an excellent example of industry and workmanship.

The same process is being successfully carried out in a young man of thirty who has done nothing for nine years except take out patents on one or two unsalable devices. His symptoms were nervousness, palpitation of the heart, and weakness. This man had to be taught not only to assume a new attitude toward his anatomically sound body, but his sympathetic wife, parents, and sister also have had to be educated. He is now working away with a determination which has come with his first real accomplishment and he is convinced that life holds much more for him than he had ever hoped for. These cases illustrate the educational value of occupation as well as its value in directing the thoughts away from the supposed ailments.

An Aid in Vocational Placement

Occupational therapy in civilian medicine has proved very useful in determining the capacity for work of patients with definite organic disease. It is difficult or impossi-

ble to say, by means of an examination alone, no matter how extensive, how much work a man can do without serious symptoms. His own history, too, is often misleading. But watch that

man at work for a few weeks and the amount and type of work he can do become clearly determined. Then vocational placement can be done with the proper medical basis. This point was well illustrated by the case of a young man of twenty-nine who, five months previous to his appearance in the dispensary, was attacked by acute articular rheumatism, which had resulted in a badly damaged heart. He had worked at installing telephones, doing both inside and outside wiring. His company, he said, was willing to continue his pay during six months of incapacity, and, as five months were already gone, the outlook for him, his wife, and two children was dark. Two or three attempts to work had only served to aggravate his symptoms, a fact that was easily understood when he was examined. His

heart was found dilated and signs of serious valvular heart disease were present. The man was sent to the shop and set to weaving for three hour periods. In a week this was increased at his request to a full day and very soon he stated that he felt distinctly better. His appearance changed noticeably; he became brighter, held his head higher and the expression of constant worry disappeared. In three weeks he had demonstrated to our surprise that he could sit and weave all day and go back and forth from his home without symptoms provided he was careful. The placement bureau then took him in hand and had him reemployed by the telephone company, but now as a checker of accounts in which his past experience was of value. This man has now been at his new work four months, is carrying on without discomfort, is earning just as much money as he did previously, and a recent examination showed that his heart is in better condition than when he left the shop.

Workshop Remedies Heart Disease

Occupational therapy has proved very beneficial to cases of heart disease and our routine now is to start it while the patient is in the ward of the hospital and have him return to the shop daily

during the period before he can resume his old work or be placed in a new job. These patients do better when they come back regularly to the shop than they do when they remain supposedly

A sufferer from heart trouble who finds relief and assistance toward recovery at the loom.

in perfect quiet at home. One patient, a man of sixty-two, was sent to the workshop after having been prohibited from working by his physician for a period of two years on account of attacks diagnosed as angina pectoris. Although his shop work, at first, required no effort, he voluntarily began to do heavier work without pain or other symptoms. And when he was discovered one day carrying cement garden benches about with enthusiasm, his physician saw the error of his prognosis. The man was told that he could go back to his old work as a furniture polisher, which he has successfully carried on now for eighteen months with renewed energy and with real joy.

Women, Too, Do Shopwork

Women work in the shop as well as men, and in several instances mothers of families have been restored so that they can take up again the laborious, never ceasing household duties greatly to the benefit of their children and husbands as well as to themselves. In one or two instances, women patients who had considered themselves doomed to lonely lives of invalidism, have discovered their mistake while in the shop and have left to be happily married.

Our experience with bed and ward occupation

has been less expensive than with the curative work-shop, but it has sufficed to demonstrate that well directed work brings with it cheer and encouragement in medical, surgical, and obstetrical wards. Basketry, toy-making, and bead-weaving can be carried on by at least 25 per cent of the patients when in bed and are used especially during the period of convalescence when patients are most apt to find fault with doctors' orders, the nursing care, the hospital food, and the administration. Work directed with cheerfulness, sympathy, and with an understanding of the patient and his condition, transforms many a patient from a grumbler to a contented and even enthusiastic hospital inmate. The expressions of interest and satisfaction which are so frequently heard from the patients are the best arguments to convince the indifferent or doubting doctor, who soon comes to prescribing work. The improvement of ward and hospital morale is striking. Work has produced a very marked effect in a ward reserved for the treatment of women with venereal disease in the St. Louis City Hospital and the nurses testify that the ward is easier to manage and pleasanter to work in.

When once occupational therapy becomes established and is properly conducted in civilian hospitals, the hospital superintendents come quickly to see how by the improvement of the spirit of their institutions their burdens are lightened and the work made more successful.

But perhaps the essential question which the doctor must seek to answer is: do these effects assist materially in restoring the deranged bodily functions, do they hasten the approach to health, and do they increase the resistance to disease? Leaving aside those cases in which occupations furnish directly the special exercise essential for the functional recovery of a joint or muscle, the question resolves itself into the effects of preoccupation and of mental, moral, and physical stimulation of well directed work. Our opinion may be emphatically expressed that occupational therapy is a curative agent of very real value in the variety of ailments met with in general civilian hospitals. It is a curative agent which should be at the disposal not only of every member of a hospital staff, but should be available in private practice. Occupational therapy should be carried to the homes of the well-to-do. Many an invalid could receive its benefits when trained teachers are ready as private practitioners to carry out the doctor's orders of prescribed work.

It is our hope then that the impetus given to work as a curative agent by the war will continue and grow for the benefit of future generations.

NATIONAL PHYSICAL EDUCATION SERVICE

With the aid of legislation, lectures, magazine articles, and the publication of pamphlets on the promotion of physical education, the Playground and Recreation Association of America, through the newly created channels of the National Physical Education Service, is striving to give impetus to the movement for universal physical education in the schools.

The Service represents the cooperative effort of more than thirty state and Federal organizations that are working to secure legislative support for a program of physical education.

DISEASE AND WOUNDS AS CAUSES OF DISABILITY IN THE ENGLISH ARMY

The compiled figures on pensions by the English Ministry of Pensions throw much light on the relative distribution of disease and wounds in the great war. While the prevention of disease in the armies has been a triumph for the physician, there has been an equal triumph in the restoration of wounded men and the relative importance of disease and wounds has not been changed as much as might have been expected.

Out of a total of 421,877 pensions granted, tuberculous and chest complaints were responsible for 47,078 or 11.2 per cent; rheumatism for 27,424 or 6.5 per cent; heart disease, 41,699 or 9.9 per cent; nervous diseases, 25,165 or 6 per cent; epilepsy, 4,257 or 1 per cent; miscellaneous diseases, including Bright's disease, debility, ulcer of the stomach, varicocèle, enteritis and malariae, spinal, appendicitis, amounted to 81,381 or 19.3 per cent.

Altogether, the number of persons pensioned on account of wounds was 42 per cent of the total as against 58 per cent on account of disease.

GERMANY'S SOCIAL INSURANCE COSTS MORE UNDER NEW CONDITIONS

The *Monthly Labor Review*, published by the Bureau of Statistics, United States Department of Labor, prints a translation of a recent article on "Social Insurance in Germany After the War," by Professor P. Moldenhauer, which originally appeared in the *Kölnische Zeitung*, in December. An unfavorable development of the actuarial bases of social insurance has come about, writes Professor Moldenhauer, who inquires whether Germany will be able in future to discharge its obligations with respect to social insurance, under conditions more difficult. He explains the problem as follows:

"The war has shifted the actuarial bases of social insurance to the disadvantage of the insurance carriers. Owing to undernutrition, women's labor in establishments not suited therefor, overexertion, excessive overtime and night work, and suspension of numerous protective regulations, the morbidity, invalidity, and mortality rates have risen. The successful combating of tuberculosis has been interfered with during the war, and the ravages of this disease have been increased by undernutrition. The unfavorable state of the health of ex-soldiers, especially of disabled soldiers, who sooner or later will file claims for pensions, must also be taken into account. The strongest evidence of this development is to be found in the sickness insurance. According to the yearbook for sickness insurance for the year 1917 the average morbidity rate in fifty-one sick funds distributed over the whole Empire rose from 2.66 per cent in 1915 to 2.77 per cent in 1916 and to 3.03 per cent in 1917. A further increase of the morbidity rate is expected for 1918. The yearbook states that, as a result, the prewar rate of contributions of 3.5 per cent of the earnings of the insured will have to be raised to 5 per cent."

THE MEDICAL SCHOOL AND CHILD WELFARE

BY FLORENCE BROWN SHERBON, A.M., M.D., UNIVERSITY OF KANSAS, UNIVERSITY EXTENSION DIVISION,
LAWRENCE, KANSAS

THE practice of medicine had its origin in the demand of the sufferer that someone relieve his pain. The primitive medicine man made a "bluff" at doing this and frequently his patients recovered, whereupon he modestly took unto himself the credit. If his patient died, he had it distinctly understood that the gods had reasons of their own for removing the sufferer in spite of his unquestioned skill.

From this crude beginning empirical medicine has come a long and hilly way, aided by the uncertain staff and script of incantation, bleeding, purging, sweating, analgesics, antipyretics, etc. With the work of Pasteur, Koch, *et al.*, a definite part of therapeutic practice became for the first time arranged in a sufficiently orderly fashion that it might be said to pass over into a science. Drug therapy has made some shift toward exchange of the empirical for an exact and scientifically ordered method of application; while the recent developments in medical biology bid fair to wipe away so many mists and clouds from our scientific horizon that one may not even venture to guess how far we soon may see into the mystery of the physical and mental complex which we call life.

Forgetting the Needs of Many

Organized medical effort still takes the original point of departure, however, and works from the pain back toward relief from the pain, and concerns itself as little as possible with the physical optimum or norm which should furnish the basis for the study of physical and mental pathology and their appropriate therapy. The chief concern of the medical school and of the medical student is to assemble a concrete unit of information and technique which will enable that student to go into a community or a hospital and diagnose disease and apply the accepted remedy of his chosen school or cult. For all purposes of immediate concern to him, humanity is divided into two classes:

FOR A HEALTHIER GENERATION

It is not beside the mark, nor should it be beneath the dignity of the Medical School, for it to formulate courses of instruction for the preparing of practitioners to meet the really fundamental and practical problems underlying the all-important and comprehensive proposition of rearing a generation of children who may be turned into the public school free from preventable physical handicap.

Once this is achieved, the mass problem of the health of the school child becomes automatically solved except so far as the school plant and school curriculum react unfavorably upon him.

nomer, since one cannot prevent and cure at the same time. It is true that a new science has arisen and we are fond of saying that it is a branch or outgrowth of the science of medicine, as if it were a part of a larger whole. This new science is very properly termed public health, and improperly called preventive medicine. Were it not more logical to recognize an all-comprehensive science of health with various subdivisions into, say, community health and sanitation, and personal health, computed on a basis of maximum personal efficiency as scientifically determined; then as another subdivision let us place the various deviations from the norm or optimum. Let these pathological manifestations then appear in their true relations and gradations, with their logical causes and remedies. Let us have primarily students of the science of health who, if you please, may elect to specialize in medicine, or in the cure of disease rather than in any of the particular phases of normal life and its conservation. The science of health, by this token, is more inclusive than the mere prevention or cure of disease, being in fact carried out to its logical limit of an ultimate maximum in the physical attainment of the race.

To illustrate the point that now we are making the whole subservient to the part, and that present-day medical education, although much the best thing in this way the world has ever seen, still falls far short of comprehending the science of health, let us consider the matter of the health of the school child.

those who need a physician, and those who do not. He has no standard for appraisal of the child or adult who does not manifest some pathology which he has been trained to recognize.

A Broadened Science of Health

Since the word medicine means "to cure," or "to heal," perhaps this limitation is legitimate. The popular term of the moment, "preventive medicine," is then a mis-

When the health of the school child became a matter of active concern the physician was called in to diagnose pathological physical conditions; then physician and educator combined forces to devise ways and means of having these pathological conditions treated and cured. Too much of the effort of the school physician must still go into this illogical process of mending what should never have been permitted to need mending. Gradually, however, the problem is assuming organic shape and at the present time a determined effort is in progress to establish, as a basis of health work for school children, a physical norm, from which the effort to achieve standardization may logically proceed. The scheme launched by the Child Health Organization, 156 Fifth Avenue, New York City, for the study of the nutrition and development of the school child, and simultaneously to enlist the child's interest in his own condition, is nothing less than inspirational. At the present time hundreds of thousands of school children are being weighed and measured, and the resulting tabulations will furnish one of the most gigantic pieces of health research ever accomplished. At the present time, however, professional physical examiners of school children are self-trained people who have added to their knowledge of the therapeutics and pathology obtained in the medical school such information concerning normal physical development as they might have the interest and initiative to get from some department of physical education, or from reading and from experience. As far as my present knowledge goes, there is no medical school which pretends to offer specific vocational training for this highly specialized, difficult, and increasingly important professional calling.

It may be that the reason for this lies in the fact that at the present time there is no accurate or scientific fund of knowledge concerning the normal development of the child. We are compelled to work by the measure of certain meager averages which we do not as yet even know how to interpret.

It would seem, however, that such knowledge as we have might profitably be assembled and imparted in an orderly manner to the would-be specialist in the health of the school child. This would economize the time and expense of the student, and make for standardization and cumulative efficiency.

The graduate of the medical school who essays the physical examination of school children for the purpose of physical evaluation, apart from the recognition of definite medical pathology, finds himself confronted by a proposition for which he

has neither chart nor compass. He knows little about the phases of growth through which the child's body must pass or the salient characteristics of each phase. He knows little, unless he be also a physical education expert, about posture, or physical measurements, or normal proportions. Still less does he know, until he learns by much experience, how to interpret the etiology of the varied and often vague nervous and nutritional manifestations which his eye will come to recognize.

School Physician Works Against Odds

It takes an unreasonable amount of this would-be specialist's time for him to train himself to recognize the manifold pre-pathological conditions which must be the basis of constructive health work for the child.

It takes an unreasonable amount of his time for him to train himself to recognize the many points of reaction of the school environment upon the child.

It takes a much longer time for him to acquire an appreciation of the diverse reactions of the home and street upon the health and physique of the child.

We are placing the school physician upon our leaking educational ship and asking him to bail out the physical defects of our school children which threaten to capsize their mental attainments. It were logical if we first trained him to stop the leaks as rapidly as possible. Instead, he must find the many leaks himself, and not only so, but he must find for himself the requisite tools for mending them. Too often he is content with bailing, and so is the school system and the community. The attitude is, "Bailing's all right as long as it keeps us afloat!"

As another illustration of a field of specialization into which the medical practitioner has been drawn willy-nilly and without preparation by the old demand of the laity for help, we will take the present movement for the health of the pre-school child.

Physical examiners of school children have been saying with increasing emphasis, as their findings have accumulated, that most of the radical defects of the school child are upon him when he first comes into the school system. So virgin a field is this pre-school health life of the child that the women physicians who first essayed in 1911 to make physical examinations of children under three years of age could find no record of measurements or averages which might be used as a standard save those contained in Dr. Holt's classic text on Diseases of Children. Naturally, these averages were found too low for the normal chil-

dren (at least normal enough to not be under physician's care) who constituted the subject of this mid-western investigation.

With the spread of the Children's Health Conference, culminating in the Children's Year drive to have every pre-school child in the United States weighed and measured within the year, it has come about that practically every physician in the United States has been called upon to pose as an expert in child development.

The average medical practitioner is nonplussed when confronted by a mother, keen for information and instruction, and one of the first naked babies he has ever seen who was not actually ill. If he does not find signs of the pathology which his eye and touch have been trained to recognize, and if the mother does not tell a story of definite ill health, he is more apt than not to mark the child O. K. and pass hurriedly to the next.

What Is Norm of Child Health?

He is at a distinct disadvantage because he has nothing in his training or experience (unless he be a father, and even then he may see little of his own child's body) to aid him in the understanding or appreciation of the many factors entering into the growth and development of the child's body. What does he know about a norm for each phase of development, and for each part of the body? A stock-judging expert has his eye trained for a norm for every feature of a young animal's body, from the shape and patency of its nose and contour of its head and neck to the quality of the tuft of hair on the tip of its tail.

Granting that the physician has fortified himself with such figures and averages as have become available with the progress of the examination movement, he still has little to help him interpret these. To be able to help the mother, he needs to know how to draw from her graphic information as to environment, habits, food, clothing, psychic atmosphere, exercise, play—in short, he must know how to get a picture of the forces that are reacting on the plastic animal before him.

Even granting that he has successfully constructed this picture, and that it appears to have convincing perspective and unity, he must further have the social training and experience to enable him to appraise the intelligence of the mother and visualize her circumstances. From all this as a basis he must formulate advice which will have some show of being understood and put into practice by the mother, or know how to put her in touch with other agencies of assistance.

For example we will take the posture of a child of three years. It will take the average medical practitioner some time after he begins to look at

naked babies to realize that there is a normal posture for a child of this age and that deviations may already occur. It will take him still longer to recognize that these deviations are significant and may have a distinct bearing upon the efficiency and symmetry of the final shaping of his body. It will take him a very long while to figure out the possible and probable reasons for deviations and get these from the mother who sits dumbly waiting for words of wisdom to fall from his mouth.

Where School Training Falls Short

The average school-trained man will recognize talipes and lateral curvature and pathologic features commonly described in medical literature. The child in question may not exhibit any of these, it may only stand with protruding abdomen, ribs touching each other like the closed slats of an old-fashioned shutter, and show feebly muscled, projecting scapulae.

The physician will be fortunate if his attention has ever been called to the loose, unstable attachment of the shoulder girdle upon the thorax, especially in the little child. He will undoubtedly have learned glibly the names and attachments of all the muscles and have an idea of how to reduce a dislocation or fracture. He will have much to learn of the structural significance of this mechanical arrangement, especially in the growing child.

Granting that this type of posture is noted, he may also note that the general body musculature is lacking in tone. He may rightly infer that better food and more outdoor activity are indicated, and inquire in detail as to diet, exercise, sleep and the various factors contributory to physical vigor.

On the other hand, he may find that the leg muscles of the child are perfectly well developed and taut; also, the muscles of the forearm may be better developed than those of the upper arm. The muscles of the chest and shoulder only will be flabby and undeveloped, allowing the arm to swing loosely, and affording insufficient anchorage to the scapula.

Faulty Posture Harms Infants

If the doctor now presses lightly on the tip of the shoulder, he will be surprised to discover how easily the entire shoulder may be inclined to the front and how sharply the scapula can be made to project in the back. If he will now notice the carriage of the head he may note that the weight of the head is allowed to hang from the posterior cervical muscles. In some cases this deflection in older children is sufficient to change the normal angle of vision, and compression by the habitually stretched muscles may cause induration and pass-

ive congestion, which are etiological factors in certain types of headache.

If the physician will now note the effect of this type of posture upon the rest of the body he will discover (if he try the experiment upon himself) that full expansion of the chest is difficult or impossible in this position. When this is habitual the chest may become muscle-bound through loss of the normal and important elasticity of the rib muscles and the normal expansion of the lungs be constantly limited. He will discover that the tipping of the shoulder blade allows the arm to make a quarter swing which points the thumb toward the back instead of the front of the body. From this position the arm and hand must make the corrective quarter turn before every use made of the hand. During a lifetime this even furnishes an item of considerable impairment in manual efficiency.

If the physician will now notice the segments into which the posture line is broken, he will notice that the forward tilt of the head has compelled the shoulders to find a stable fulcrum in a compensating tilt of the pelvis. This, of course, breaks up the normal relationship of legs and feet and throws the weight center in the wrong place on the foot.

It would make one of many possible subjects for particular investigation associated with this one posture-complex if someone would figure out the probable relationship between this tipping of the pliable pelvis of the female child and malformed pelvis in child-bearing women.

Causes of Child's Wrong Posture

So much for some of the items the physician will train himself to see in a child who may present no organic or strictly pathologic defect. The possible causes of this posture and their appropriate correction is another chapter of the story.

Unless this physician has been minutely observant of ordinary household life and of the daily regimen to which the ordinary child is subjected, it will take him a long time to discover that this child has probably been restricted in its activity to strictly leg and forearm movements; that he has not been permitted to climb or suspend his weight by his arms. He makes small movements with his hands, but almost no whole-arm movements; that there is nothing in the home of the correct size for him to sit upon; that he must crouch over his playthings on the floor or climb into an adult chair; that he has not been encouraged to crawl on all fours, which is nature's way of properly aligning the mechanism of the shoulder girdle; that his stockings have been adjusted for a year or more of his life, even at the age of

three, so that all the pull of their support comes upon the most easily deflected point in his mechanism, viz., the tip of the shoulder.

Physician's Advice to Mother

Other factors may contribute to this condition, including an habitually over-distended abdomen; tying into a buggy for long hours in an over-flexed position; sleeping in too short a bed, etc.

Even after all this has been brought into the focus of the physician's attention—the person from whom this mother must get help, if she is to get it at all—he has still to construct a program of correction. If he is to meet the needs of the child he must outline to the mother a scheme of play which will call into use this most important and entirely neglected part of its undeveloped body. He must tell her how to make simple and inexpensive play equipment which the child will use through pure enjoyment. He will have to explain to the mother of the creeping child the necessity of crawling, the necessity for a play pen, and untrammelled activity. He will bespeak the little chair and play table which are as much the right of the child as are the chair and table of the adult. He will have to overcome the fear of the mother that the child "will hurt itself." He will have not only to show her wherein the clothing is deforming the plastic form of her child, but will have to explain the principle of the correct suspender supporter.

I have hoped to show by this one concrete illustration how closely disease and health are linked together with the intimate, minute, and more or less petty concerns of life, and make the point that effective preventive work must go straight to the humdrum facts of everyday life and establish there a stable point of departure. To be able to do this effectively requires specialized training in method and attitude and to a certain extent in subject matter, and all directed toward the establishing of normal standards of living.

Keep Pre-School Child in Health

The one branch of public health work which is at present well ordered and effective, viz., sanitary science, goes straight into the intimate details of personal and family life. An investigation of an epidemic may end in the question of how a woman washes her milk cans, or whether a baker washes his hands on coming from the toilet. The most trivial human act may have an important bearing upon the health and efficiency of the individual and the community. It is not beside the mark, nor should it be beneath the dignity of the so-called medical school for it to formulate courses of instruction for the preparing of med-

ical practitioners to meet the really fundamental and practical problems underlying the all-important and comprehensive proposition of rearing a generation of children who may be turned into the public school free from preventable physical handicap.

Once this is achieved, the mass problem of the health of the school child becomes automatically solved except so far as the school plant and school curriculum react unfavorably upon him. Spe-

cially trained experts should be forthcoming adequately to safeguard the school life of the child. With this constructive, far-reaching program accomplished there need be no fear of the revelations of another draft.

To accomplish the assembling of a really protective health machinery we must eventually reverse our present order of attack and emphasis and start with the establishment of normal values as fixed points of departure.

LAW FOR THE DOCTOR—HIS LIABILITY FOR FAILURE TO DIAGNOSE DISLOCATION OR FRACTURE

BY LESLIE CHILDS, ATTORNEY AT LAW, INDIANAPOLIS, IND.*

ALLEGED failure to diagnose fracture and dislocation has been the starting point of a considerable number of damage suits against physicians and surgeons. In fact, this particular phase of alleged malpractice has been so thoroughly thrashed over in court rooms that a reading of the reports on cases of this kind would tend to qualify even a truck driver as an expert on dislocations and fractures.

About the only undisputed fact threading its way through the entire argument appears to be that a fracture is in many cases extremely difficult to discover. This fact alone has saved quite a few physicians and surgeons from having to shoulder judgements for alleged malpractice. But once in awhile there appears a case wherein the actions of the defendant physician have been so apparently at variance with the customs of the medical profession that even this fact fails to save him. Such a case was that of Foote vs. Bonnet, 47 Col. 282. The case is an interesting one not only from the point of the facts therein but from the method of defense, or rather lack of defense, employed by the defendant.

Emma Foote, the plaintiff, fell upon the sidewalk one evening and Dr. Bonnet, the defendant, was summoned, arriving a few minutes later. He found the patient suffering severe pain, and expressed the opinion that she had sustained a fracture, but advised her that he would not make an examination until the following morning. The next morning he called and examined her hip by feeling it with his hands and concluded that the injury was a severe bruise and not a fracture; thereafter he treated her for a bruise.

He called and treated her twice a day for about two weeks, and thereafter once a day for about

one month, and after this period occasionally for about two months. During this time he made frequent examinations of the injured limb, took measurements to ascertain whether or not it was shortening, but at no time regarded the injury as anything more than a severe bruise. The patient was confined to her bed for about four weeks; thereafter she was able to walk with crutches, and about four months after the injury she had sufficiently recovered to go to Santa Fe where she remained for several months.

She was compelled to use crutches, or a crutch and cane, for about eighteen months after the injury, and thereafter she used a cane only. She suffered pain more or less for about two years at the end of which time it passed away but would occasionally return. The injury caused a shortening of the right limb of from two to three inches.

During the trial of the case a physician and surgeon testified for the plaintiff substantially as follows:

That about five years after the injury he examined the injured limb, aided by an x-ray photograph, and that this examination showed that the plaintiff had sustained a fracture of the neck of the femur. He admitted that in a fracture of this kind it was often very difficult to ascertain whether there had been a fracture or not; and further, that a severe bruise in the vicinity of the neck of the femur would produce practically the same pain as a fracture. He also detailed the usual method adopted by surgeons for ascertaining whether or not, when the hip is injured, a fracture exists. It appeared from the testimony that Dr. Bonnet had not adopted this method, nor done anything more than has been stated. During the examination of this witness he was asked :

Q. Doctor, if a patient with an injured hip

*The second of a series of articles on "Law for the Doctor," written for MODERN MEDICINE by Leslie Childs.

lie on the back and her foot turns over to one side, what is the indication?

A. Might be a fracture, might be a dislocation.

Q. Would it be one or the other?

A. One or the other.

Q. The indication would be that it was either a dislocation or fracture?

A. Yes. That is, if there was inability to put it back again in place.

The plaintiff was recalled as a witness and was asked:

Q. You may state to the jury what position your foot—the right foot—assumed after this injury, when you were lying there on your back.

A. It lay over on the side.

Q. Did Dr. Bonnet ever see it lying over on the side?

A. Yes, sir. He said he did not like it, although he could not understand why it did that.

Q. Did he straighten it?

A. He straightened it up, and it fell back again.

Q. Did you have any control over it to keep it up from falling back?

A. None whatever.

There was no testimony from the defendant, or in his behalf, that would controvert the facts and evidence as given above for the plaintiff. In summing up the court in part said:

"From these facts and evidence it is clear that the injury to plaintiff's hip was a fracture instead of a mere bruise, and the question to determine is whether or not it appears that defendant was guilty of negligence in diagnosing and treating her injury; * * * the law implies that a surgeon * * * possess that reasonable degree of learning and skill * * * which is ordinarily possessed by others of the profession; second, that he will use reasonable and ordinary care * * * to accomplish the purpose for which he is employed; * * * either defendant did not possess that degree of learning and skill which the law requires of surgeons, or, if he did, he failed to exercise ordinary care in applying it."

The Supreme Court thereupon affirmed the judgement for \$1,500 damages that had been awarded the plaintiff in the lower court.

Official Surgeons Plan Convention

The American Association of Official Surgeons will assemble at Chicago, September 15 to 17, for the thirty-second annual convention of the organization. The meeting will take place at the Congress Hotel. Operative demonstrations will be held at Chicago hospitals.

Make Study of Heating Problems

A better conception of the requirements of heating and ventilation, and a wider application of improved standards, are to be expected in the next few years as the outcome of extensive, well-financed arrangements which have been made for study of heating and ventilation problems both by the United States Bureau of Mines and by the

American Society of Heating and Ventilating Engineers. The Society has organized a Bureau of Research and has named John R. Allen, Professor of Mechanical Engineering, University of Michigan, as director. Other engineering societies are cooperating in the surveys. The Bureau of Mines has an annual appropriation of \$40,000 for the work.

REVIEW OF PUBLIC HEALTH LEGISLATIVE PROJECTS

A review of the recommendations of the governors of the states made to the legislatures of 1919 indicates an intensive interest in the subject of the health and well-being of the people. This was to be expected in view of the influenza epidemic, and particularly in view of the disclosures of the draft regarding physical preparedness and the recognition of the supreme need of strong national vitality. Thirty-two governors made recommendations regarding health covering the subject of strengthening the state health departments, the control of venereal diseases, the development of full-time health officers, physical education, medical inspection of schools, housing, industrial health and safety, the control of tuberculosis, child welfare, and the care of the feeble-minded.

Goodrich Advises Corrective Training

Governor Goodrich, of Indiana, after pointing out the evidences of physical defectiveness as indicated by the statistics of the army, said: "The health authorities all agree that most of the defects and disabilities of these men were due to conditions that might have been prevented or cured in childhood. Physical education is as necessary to the development of our young people as mental training." He recommends compulsory physical education and full-time public health officials. He further recommends the enlargement of the provision for the care of the feeble-minded, including the establishment of a colony.

Governor Lowden, of Illinois, recommended as a health measure the limitation of women's work to eight hours. He also made strong recommendation for a state housing code, declaring that "one of the most frequent causes of disease and debility is improper and insanitary housing. This is probably the largest single cause contributing to tuberculosis. * * * It is not enough that the State care for its dependents; it has a right, as it is its duty, to prevent such dependency wherever possible. Other states long since have enacted laws to prevent the building of houses which would be inimical to the public health."

Governor Smith, of New York, commended the work of the commission investigating the subject of the feeble-minded, and urged the adoption of the program which they submitted. He also recommended that a larger protection should be thrown about children at work, declaring that "no children should be allowed in any occupation injurious to health and the provision requiring physical examination of children should be extended to all employments in which they are engaged." He also took strong ground on the cost of milk, declaring "the present high cost of milk is a public menace. It is unnecessary to describe the misery, disease, and death that follow an inadequate milk supply." He proposed the appointment of a commission to investigate the distribution of the milk supply.

Proposes Revision of Health Laws

Governor Townsend, of Delaware, urged as a part of the reconstruction program a revision of health laws and administration, and promised specific recommendations.

Governor Holcomb, of Connecticut, confined his special recommendations on health to matters concerned with child welfare, and especially the matter of infant mortality. "Every year," he said, "among children less than five years of age, we witness an excessive mortality without its causing much perturbation of spirit. This emphasizes our full responsibility for permitting preventable waste of human life. We have been intelligently concerned about preserving animal life and have carefully provided for the examination of cattle for tuberculosis and of swine to prevent hog cholera and have created a commission to detect and eradicate such diseases among our animals, but we have not been equally or intelligently solicitous of the health, life, and welfare of our children, but have left it to the efforts of charitably disposed citizens."

Governor Brough, of Arkansas, emphasized the necessity of a strong state department of health, and recommended especially the creation of a state sanitary engineer. He further emphasized the necessity for more complete vital statistics and for the drastic control of venereal diseases. He commended the Bureau of Sanitation which has control of the licensing of hotels and rooming houses, and urged an appropriation of \$12,500 for a special campaign against malaria.

Governor Burnquist, of Minnesota, laid emphasis upon sickness in rural districts as follows: "The Legislature should also devise some plan for taking care of the rural health situation, especially in certain portions of this State, where there is a lack of medical aid. The same fight against preventable diseases that is made in cities should be made in the rural districts. More health inspectors should be provided for the country and in communities where hospital facilities are needed they ought to be provided by the State to a greater extent than heretofore." He also recommended the consolidation of state, public health administrative offices, and a large appropriation for the prevention of venereal disease. After commenting on the army statistics he declared for physical training and medical inspection in schools.

Governor Edge, of New Jersey, recommended effective measures for education in health and for child hygiene, saying: "The operation for the national selective service regulation disclosed a percentage of physical disability wholly inexcusable in an enlightened age." Further, he said: "The war has taught us the value of preventive medicine and has given physicians and nurses equal eminence as educators with teachers in our schools and colleges. It has taught us the necessity of a new and more understandable relationship between the home, the school, and the factory; that we must employ the powers of government to protect the bodies of our school children and our young workers from impairment, to save their brains and their souls from starvation."

Pennsylvania Wants Housing Control

Governor Sproul, of Pennsylvania, declared strongly for more complete control of housing problems. "Our larger communities," he says, "can take care of themselves in these matters, but throughout the State there are places where people are living in frightfully insanitary homes, surrounded by conditions which make for bad health and bad citizenship. Especially is this true in some industrial settlements where families are compelled, in order to be near their employment, to live in places which are unfit for human habitation. We ought to have the power to help in this very important matter."

Governor Bartlett, of New Hampshire, recommended enlarged provision for the State Department of Health and urged that a plan be developed for cooperation with

the State College at Durham as a step toward efficiency.

Governor Stewart, of Montana, urged that ample means for meeting contingencies such as the influenza epidemic be given to the State Department of Health. He recommended, also, a survey of the feeble-minded in Montana.

Governor Gardner, of Missouri, recommended a greatly enlarged state health control with an adequate state health department having control over health work throughout the State and full cooperation with the Federal government in the control of venereal diseases.

Governor Cox, of Ohio, made one of his principal recommendations the necessity of reorganizing local health administration, abolishing the 2,100 local health officers and substituting all-time county or district health officers in their places. He also made urgent recommendation concerning the control of venereal diseases.

Governor Sleeper, of Michigan, made similar recommendations for an all-time health officer in each county, working under the State Department of Health.

Urge High Standard of Housing

Governor Coolidge, of Massachusetts, under the title "Man Power" declared: "The salvation of a state, in peace no less than war, depends upon the effectiveness of its population. To secure and promote this the protection of the public health is fundamental. This means, in the first instance, preventive measures. With many of these we are already familiar, and others will be established by research. For such purpose it is recommended that provision be made." More adequate study and provision for the feeble-minded was also recommended. He likewise urged the maintenance of high standards of housing and working conditions, saying: "That same watchful care which has surrounded legislation of housing, sanitation, housing of labor, and conditions of employment in different occupations must be maintained." In a striking passage he said: "No progress was ever made by regarding mankind as cheap."

Governor Milliken, of Maine, recited the necessity of having supervision of health by experts trained in public health and sanitation. He recommended the enactment of a law authorizing towns to combine into districts for the employment of health officers, and that a part of the salary of such officers should be paid by the State. He further urged greater care of children as follows: "It is clearly our duty to insist upon dental and medical examination and treatment of school children, as well as proper physical exercise and playground activities under competent supervision."

Governor Harding, of Iowa, declared for some system of universal service "not so much for the purpose of making soldiers with which to contend on the field of battle as to create an increase of man power to work together in harmony and equality in the battles of peace." He pointed out the appalling number of men "who are physically defective so that they are constantly working under handicaps." Commendation was given to the completed establishment at the state university of a hospital for the care of diseased and crippled children.

Governor Larrazolo, of New Mexico, urged the establishment of a State Department of Health to consist of a commissioner of health and a public health council composed of five members, three of whom should be regularly licensed physicians. He urged that the department should have ample funds. Child conservation was given urgent recommendation.

Governor Boyle, of Nevada, made this interesting observation: "While the State has, through the agency of the

Veterinary Control Service and through the Livestock and Sheep Commissions, made ample provision for the quarantine and proper care of animal diseases, it has allowed the public health laws to lag far behind those of other states which profess to consider this question as important." He said that the Board of Health had been nothing more than a bureau of vital statistics, and urged that the Board be given ample power to meet its proper duties.

Governor McKelvie, of Nebraska, made very urgent recommendations for the control of diseases of farm animals but there appears to be no suggestion in his message concerning the health of human beings. Concerning tuberculosis of cattle, he said: "The enormousness of the loss of farm animals from contagious and communicable diseases and plagues is such that this subject needs prompt and vigorous attention. The most insidious and dangerous of all these diseases is tuberculosis. The Federal government has appropriated a liberal sum for inspection, testing, and indemnification in the control of tuberculosis and the states are called upon to co-operate with both inspection and money. I believe this should be done." It would be somewhat fitting if he had followed this with a similar recommendation concerning tuberculosis among human beings.

Governor Frazier, of North Dakota, urged proper health protection, a full-time state health officer, county health boards accountable to the State Board, and a county school nurse.

Pickett for Compulsory Physical Education

Governor Pickett, of North Carolina, declared strongly for the providing of an appropriation for mental defectives, and urged that marriage licenses be prohibited "to a man afflicted with a contagious disease due to vice." In regard to child care he said: "Every child has a natural right to have every mental and physical defect corrected if it be in the power of medical and surgical skill." "We cannot claim," he said, "to maintain an intelligent, much less a Christian, civilization if a child be allowed to stagger through life under the handicap of a mental or a physical infirmity for the want of a few dollars. Indeed, it is an economic blunder for society to permit an adult to become a mental or physical derelict for want of proper surgical or medical treatment." He urged physical examination of school children and compulsory physical education.

Governor Carey, of Wyoming, urged that the State Board of Health be given full authority and that a full-time state health officer be provided. He also urged that there should be established a laboratory where examinations of a pathological nature could be made. He made this observation: "We are spending large sums of money to protect our livestock from disease, but I fear we have been overlooking the welfare of our people."

Governor Cornwell, of West Virginia, urged the strengthening of the State Health Department. "Its activities must no longer be confined to dealing with epidemics, but it must consider the dissemination of information regarding preventable diseases as well as bettering general health conditions through better sanitation, better food, and better water." He calls attention to the increased use of habit-forming drugs and urged the strictest legislation regarding their sale.

Governor Lister, of Washington, urged larger appropriation for the State Board of Health and especially for enlarged service for the control of venereal diseases.

Governor Graham, the retiring Governor of Vermont, strongly urged medical inspection in schools and the re-

tention in institutions of inmates until cured of venereal diseases, and an enlarged appropriation for fighting tuberculosis.

Governor Norbeck, of South Dakota, strongly recommended health inspection in public schools and the employment of a nurse or health instructor in schools.

Promote Doctrine of Sanitary Living

Governor Manning, of South Carolina, urged better housing conditions for the poorest mill worker and tenant farmer "and the dissemination into the isolated rural sections of the doctrine of sanitary living so that the people may be taught to prevent disease and to treat it when it falls upon them." Without specific recommendations, he set forth a vision of general public welfare.

Governor Beeckman, of Rhode Island, confined his recommendations concerning health to child welfare and urged that effort should be "directed to the prevention of those harmful conditions which destroy or limit the child's chances of developing into a healthy and mentally well-balanced member of the community in which he lives.

Governor Brumbaugh, the retiring Governor of Pennsylvania, strongly commended the State Department of Health and urged the full support of the Assembly.

Governor Withycombe, of Oregon, suggested the desirability of establishing a hospital for industrial cripples in conjunction with the University of Oregon Medical School, and that a section of this hospital be devoted to the care of indigent and crippled children.

Governor Robertson, of Oklahoma, pointed out that the recent epidemic had emphasized in an appalling way "the inadequacy of the resources available to our State Health Department, both as regards the size of the organization and the equipment at its disposal." He urged a material increase in appropriation and recommended the establishment of a special bureau of tuberculosis. Further, he urged the necessity of providing inspection in the public schools as well as physical examination of all persons handling food and drink for the public. He also called attention to the necessity of strengthening the cooperation with the Federal government in the fight against venereal diseases.

[A complete review of new health laws will appear in a later issue.]

A MEDICAL BASIS FOR MENTAL HYGIENE

A sound medical knowledge, coupled with a thorough understanding of psychiatric principles, is essential in the equipment of persons who attempt to determine and classify the mental states and ages of children by the use of psychological tests and other means, asserts Walter L. Treadway, assistant surgeon, United States Public Health Service, in *Public Health Reports*, April 11, 1919.

Without the proper medical knowledge and psychiatric study, the investigator will be apt to wrongly classify cases of retarded mental development as feeble-mindedness, or he will fail to grasp clearly the distinctions that separate the borderland cases, in which normal mental development may be attained between childhood and maturity under favorable conditions.

Something should be known of a subject's total mental make-up, including heredity, environment, educational opportunities, and his general health. Retarded mental growth is sometimes the result of physical defects that might be corrected.

Dr. Treadway's paper bears the title, "Some Observations on Mental Defectiveness and Mental Retardation Among Children."

THE MONTH IN MEDICINE

Survey of Current Medical Literature with Editorial Comment

WALTER W. HAMBURGER, M. D., *Editor*

MEDICAL EDUCATION AS REVEALED BY THE WAR

THE effect of the war has been particularly noticeable in medical education and has disclosed many defects and deficiencies in the plan and product of our medical education which in our contentment before the war were unrecognized.

A number of articles under the above title have appeared within recent months. The first, by Edward L. Munson,¹ Brigadier General, General Staff, United States Army, read before the Fifteenth Annual Conference of the Council on Medical Education, called attention to weaknesses in the qualifications of candidates and in the qualifications of alleged specialists and to various other deficiencies of medical education. In a letter to General Munson Dr. Vaughan brought up certain additional points particularly referable to a comparison between the medical officers of the Reserve Corps and those of the Regular Army. In his reply General Munson emphasized the following suggestions for more careful scrutiny of candidates to the degree of Doctor of Medicine:

a. That all candidates for matriculation to the degree of Doctor of Medicine be given psychologic tests to determine their possession of mental qualities suitable for effectively taking up such an exacting science. These tests are now being employed in the hiring of artisans, clerks, etc., with a view to determining probable efficiency in their less scientific vocations.

b. That medical schools whose curriculums still appear substandard or imperfect institute proper remedy.

c. That such measures be taken as may be possible to insure that practitioners shall not unduly retrograde professionally after graduation. Some influences operating to interfere with keeping up with professional progress are personal problems relating to initiative, finance, environment, or other matters. Others may be favorably affected through medical societies, meetings, etc. The encouragement of the profession, and especially of the less equipped type, to take postgraduate courses of study at periodic intervals would be very valuable.

d. That more exact standards of qualification in cer-

tain important specialties be required, and that those be recognized by special degrees or certificates, as is now the case, for example, with the Doctor of Public Health degree.

The most recent contribution on this important problem is that of Foster,² who was chief of the medical service of three military hospitals during the period of the war. He brings out some very valuable and stimulating points. He speaks of his early impressions of the medical officers who passed under his observation as a painful revelation and that "the grade of medical competency which was brought out in the military hospitals came as a shock. There can be very little question that medical inefficiency is much more widespread than we have been willing to admit." He notes an instance of one of his young officers who, in spite of having graduated from a Grade A school and having had a good internship in a general hospital, could recognize no clinical picture that required a physical examination and knew nothing of differentiating systolic and diastolic murmurs. The undergraduate teaching of this particular officer had been of the lecture-demonstration-clinic variety. No actual personal instruction had been given. Foster comments further, that the majority of these young, rather untrained medical men retained potential growth and that they developed and grew as they were taught and helped. His summary of his impressions of the general practitioners who came to his notice at camp and hospital is stated as follows:

1. The practitioner of this class cannot differentiate a systolic from a diastolic murmur; in consequence, he is wholly incompetent to express an opinion about a cardiac disorder.

2. He cannot differentiate pleural effusion from pneumonia. He has never done a thoracentesis, so he cannot correct his own tendency to error.

3. He cannot recognize meningitis and has never done (often never seen done) a lumbar puncture, hence he cannot treat the disease.

As Foster properly points out, matters as fundamental as these form the keystone of medical diagnosis and without it the structure collapses. To my mind the most valuable portion of Foster's

¹ Munson, Edward L.: The Needs of Medical Education as Revealed by the War. *Jour. Am. Med. Assn.*, 1919, lxxii, 1050 and 1095.

² Foster, Nellis B.: Medical Education as Revealed by the War. *Jour. Am. Med. Assn.*, 1919, lxxii, 1540.

brief article is his insistence upon the frank and honest recognition of the defects of present medical education in order that progress toward betterment may be made and that scientific care of the sick can be taught only in one place and in one way: that is, in the hospital ward and taught by competent physicians at the bedside with a small group of students; that the art of diagnosis is the ability to examine a patient and gather the important data and properly interpret the findings; and, finally, that the general practitioner is inefficient because he does not know how to examine a patient.

Comment. It may be permitted the writer of these lines to say that during the war he was chief of the medical service at a base hospital for a period of fifteen months, and that many of the points which Dr. Foster brings out have likewise been his experience. During the early months of the mobilization of the draft in the fall of 1917 the general practitioners which were assigned to the medical service were for the most part men of from forty-five to fifty-years of age, men who, as some one has said, could not tell a "rôle from a steam whistle" and who when in college did not burn enough of the well known midnight oil. After graduating and entering into their own communities they ceased to read and develop, became interested in farming and banking, but still constituted the only available practitioners in their communities. Acting as ward surgeons, these men, although the best fellows in the world, kindly, friendly, always ready to sit down and smoke and talk, were at a loss to differentiate a scarlet from measles, a diphtheria from tonsilitis, knew when a meningitis suspect came into its ward the man was seriously sick, but did not know how to elicit nor to interpret a Kernig, opisthotonus, a Brudzinski, not to mention the intricacies of a lumbar puncture and intra spinous therapy.

Later on in the winter and spring of 1918 a different type of medical men was sent to the base hospitals, younger men, either just out of medical schools or hospitals, or men who were ambitious and rather self-sufficient but who, as Foster has said, in many instances could not differentiate a systolic from a diastolic murmur. These men were the material that we had to work with in the care of seriously sick young soldiers and it will always be a miracle that we got by as well as we did. However, with patients, and clinics, and lectures and demonstrations, and bedside teaching, many of these originally rather poorly trained men developed wonderfully. I remember in particular one man from a small school in Kentucky who when he came in was thoroughly in earnest but

poorly trained. Within six months he became one of the most valuable men in the hospital and was put in charge of the contagious group of wards; he developed into a most remarkable expert in the differentiation of skin rashes, chicken-pox, small-pox, erysipelas, meningitis, etc., etc.

One cannot help feeling that the sum and substance of this is that (1) a large percentage of our medical graduates are really very imperfectly trained in medical schools and hospitals; and (2) that, whatever their training and experience have been in schools and hospitals, they seldom add to these after graduation and establishment in practice. Almost everyone who had the responsibility of a service during the war will agree to this, and it would seem that a frank acknowledgment of the situation is necessarily a prerequisite to better things. It is not as General Munson says a question of psychological tests as to fitness, but a question whether in doing his medical school and hospital course the student was given "practical, intimate instruction in the art and science of diagnosis, and whether he was taught to examine patients with the same minuteness and thoroughness of analytical method that is used in the bacteriological laboratory in the differentiation of bacterial types."

The teaching of clinical medicine should not be an attempt, at least at first, to make a diagnosis, but it should be the teaching of *methods* of examination and the teaching and re-teaching of every careful method of eliciting important pathological data. The author for years has in his small clinics insisted upon this point—that the student should by the actual doing acquaint himself with (1) how to feel the spleen, (2) to locate the edge of the liver, (3) to percuss out the left border of the heart, (4) to hear a presystolic murmur, (5) to recognize an accentuated second aortic tone, etc., etc. The interpretation of the significance of these findings will come later; but he must first learn how to use his fingers, his eyes and his ears.

The second point, that is, the development of the doctor after he has left the environment of the school or hospital with all the new attractions and interests that claim his attention in his home community, is indeed difficult. He finds it hard to remain true to his initial youthful enthusiasm. It seems to me that the only way this can be accomplished is so to stimulate the student in his years at school to find truth for himself, in other words so to instill the love for investigative and clinical work, that this desire for scientific truth will remain with him long after he has left the medical center and will guide his interests years later. This, of course, is a more difficult problem, and certain aids such as medical societies, oc-

casional sojourn for postgraduate work are well in themselves; but the real defects in medical education are the defects of teaching and teachers, and the fact that the spirit and the urge of scientific investigation through careful examination of patients was not given these young men at the time when they could best receive it.

SURGERY AND DIETETICS

Recently some one has again said that progress in surgery is to be expected along physiological and chemical lines. This has been appreciated and anticipated by the leaders of the surgical profession for several years. As recently as five years ago it seemed almost heresy for a potential surgeon to put in a year of graduate work in a chemical laboratory. That surgery is developing through the aid of the more fundamental medical sciences is emphasized in a practical manner by Clark's³ contribution on the "Effect of Diet on the Healing of Wounds." This work apparently was stimulated by the work of Hooper and Whipple on blood regeneration after anemia, showing that the rate of blood regeneration on a meat diet is extremely rapid (a matter of days or a few weeks), whereas on a diet of starches and carbohydrates it is very slow (months being sometimes required for complete regeneration). Clark used twelve dogs, putting three on each of the following diets: (1) a mixed diet of butter, meat and bread; (2) a purely carbohydrate diet of bread; (3) a protein diet of lean meat; and (4) a pure fat diet. The dogs were fed on these diets for three days before the wounds were made. Under ether anesthesia a large and a small circular skin-flap was made on each side of the back. As criteria of healing he used Carrel's division of (1) the quiescent period during which time there is no contraction of the wound; (2) the period of granulous contraction; (3) the period of epidermization, and (4) the cicatricial period of complete healing.

The results of these studies are extremely interesting, Clark concluding as follows: "The length of the quiescent period of wound healing is affected by the diet, varies from zero in protein-fed dogs to six days in the fat-fed animals.

. . . As a consequence, the date of final healing differs by about five days for the protein- and fat-fed dogs. When the second period, or period of contraction, has set in, the rate of contraction is not affected by the diet. It is gov-

erned by a variable factor depending upon the age of the wound, and a constant factor proportional to the original size. The period of epidermization is independent of the size of the wound.

Comment. This is preliminary work which was left incomplete because of Dr. Clark's death and is published by Janet Howell Clark. It will need amplification and confirmation; but, assuming that this will occur, and since from the careful manner in which these experiments were made, confirmation seems likely, it opens up many new lines of thought and interest in the healing of wounds. The practical application is obvious and it is to be hoped that further careful work by competent observers will shortly be published and that as soon as it is placed upon a firm laboratory basis practical clinical application will be made. Possibly even this might be justified at present and no doubt clinical surgery will watch the development of this application of dietetics to surgery with kind interest and appreciation.

INJURY TO THE LIVER FROM CHLOROFORM ANESTHESIA

Delayed injury to the liver following chloroform anesthesia is an old problem among surgeons and has been reported officially since 1850. Much clinical and experimental effort has been directed toward the solution of this serious anesthetic complication. Davis and Whipple⁴ present interesting data on the influence of fasting and various diets in the liver injury from chloroform anesthesia. After reviewing the experimental work on this subject with particular reference to Opie's work on rats in chloroform poisoning, they report some feeding experiments on young dogs and puppies, feeding them on special diets and starving some before anesthetizing the dogs with chloroform. During the chloroform anesthesia a laparotomy is performed and a part of the liver removed. The details of their experimental work are too extensive to comment upon individually and those interested are referred to the original article; but the conclusions of Whipple and Davis are of distinct value.

"Starved animals are all susceptible to liver injury from chloroform. The maximal injury is to be expected.

"Sugar, and diets rich in carbohydrates fed in the days preceding the chloroform anesthesia exert a marked protective action against liver injury.

"Fat alone or in combination with food containing fat in large proportions induces a maximal amount of liver injury comparable to starvation.

³ Clark, Admont H.: The Effect of Diet on the Healing of Wounds. Bulletin of the Johns Hopkins Hospital, 1919, xxx, No. 339, p. 117.

⁴ Davis, N. C., and Whipple, G. H.: The Influence of Fasting and Various Diets on the Liver Injury effected by Chloroform Anesthesia. Paper I. Arch. Int. Med., 1919, xxiii, No. 5, p. 612.

"Beef extract has little protection in proportion to its actual food value.

"Skim milk and commercial casein or in connection with cracker are highly protective diets."

No single theory so far adopted will explain this therapeutic action of certain food substances against the liver action of chloroform anesthesia. It certainly is a reaction of the liver cells, not of substance circulating in the blood stream.

These facts should not be lost sight of in the management of any human cases in which chloroform is indicated. The patient should be given liberal amounts of carbohydrates and skimmed milk for at least two days preceding the anesthesia. It cannot be too often emphasized that it is most dangerous to give chloroform to men or animals whenever a fasting period has preceded the administration of the anesthetic.

Comment. Comment is hardly necessary on this work of Davis and Whipple as there is little doubt but that in children and in operations slight in character in which chloroform in greater or less amounts is used or indicated that the carbohydrate-milk diet preceding the chloroform anesthesia will rapidly come into general use, and that the practice of fasting prior to the administration of the anesthesia will be discontinued. Davis and Whipple⁶ in their second paper on the influence of drugs and chemical agents in liver necrosis and chloroform anesthesia come to other interesting conclusions. They take issue with Graham's theory that in the presence of water and oxygen in the body chloroform is split, that hydrochloric acid and carbon dioxid are formed, and that the hydrochloric acid kills a certain amount of liver parenchyma either by chemical action or by secondary asphyxia. Their conclusions from their experiments, considered from a practical standpoint, emphasize the value of epinephrin (adrenalin) and quinin as drugs which will to a great extent prevent liver necrosis following chloroform anesthesia, and they comment that "although chloroform is losing favor as an anesthetic, it is still employed extensively by some physicians. In view of the therapeutic use of such drugs as epinephrin and quinin, it might be well to call attention to the possible practical value of these drugs. In cases of pernicious vomiting, for instance, it would be very dangerous to use chloroform because of the starved tissues, but it might be possible to lessen the tissue injury by means of the drugs mentioned. Epinephrin subcutaneously or intramuscularly in the days preceding anesthesia exert a distinctly protective action against chloroform injury."

⁶ Davis, N. C., and Whipple, G. H.: The Influence of Drugs and Chemical Agents on the Liver Necrosis of Chloroform Anesthesia. Paper II. Arch. Int. Med., 1919, xxiii, No. 5, 636.

MENINGITIS

Progress in the study of the pathogenesis and treatment of meningitis continues. Herrick's original contributions emphasize the importance of the pre-meningitic stage of the disease, the frequency of meningococcal sepsis, and the value of intravenous therapy in meningitis. The most recent contribution from this author⁷ calls attention to so-called extrameningeal meningococcal infection in which paper he reports six cases of meningococcal infection in which meningitis was absent or played a subordinate part in the diseases process. These six cases he lists as follows: (1) meningococcus sepsis without meningitis, either clinically or at necropsy; (2) meningococcus sepsis without clinical meningitis. At necropsy the arachnoid showing beginning edema and hyperemia, the earliest stages of meningitis; (3) subacute meningococcus sepsis, but without other symptoms of meningitis except polyarthritis, in which recovery took place without intravenous treatment; (4) meningitis tarda with prolonged premeningitic stage of meningococcemia of several weeks' duration. Empyema of all accessory sinuses without meningitis; (5) local extrameningeal meningococcus lesion—pleurisy with meningococcal empyema of chest; (6) local meningococcus infection of all the accessory nasal sinuses without meningitis. The author concludes that the term epidemic cerebrospinal meningitis should be abandoned, and the term meningococcus infection should be used to denote such general processes as meningococcus sepsis. Meningococcus meningitis should be the term applied in cases of meningococcus infection with predominant cerebrospinal symptoms.

Several camp reports of meningitis bear out many of the contentions of Herrick, particularly as to the value of intraspinous treatment. Camac and Bowman⁸ speak of the value of intravenous treatment, and instance some cases in which intravenous therapy has attained results when the intraspinous method failed. Stone and Truitt,⁹ reporting on 215 cases from Fort Riley, reach similar conclusions. They particularly emphasize the importance of early energetic treatment and recommend the following plan:

First day: One intravenous injection of from 60 to 80 cc. of serum and two intraspinous injections of from 30-40 cc. each after spinal drainage of from 45 to 55 cc. of fluid, depending upon its pressure.

⁷ Herrick, W. W.: Extrameningeal Meningococcus Infections. Arch. Int. Med., 1919, xxiii, No. 1, p. 109.

⁸ Camac, C. N. B., and Bowman, K. M., Fort McPherson, Ga.: Epidemic Cerebrospinal Meningitis as Observed at General Hospital No. 6, Fort McPherson, Ga., Winter of 1917 and 1918. Arch. Int. Med., 1919, xxiii, No. 1, p. 17.

⁹ Stone, Major Willard J., and Truitt, Major Ralph C., P., Fort Riley, Kansas. A Clinical Study of Meningitis Based on 215 Cases. Arch. Int. Med., 1919, xxiii, No. 3, 283.

Second day: The same, except that from 80 to 100 cc. of serum should be given intravenously, and two spinal injections.

Third and fourth days: If necessary, repeat.

Fifth to eighth days: One spinal injection.

Ninth and tenth days: One spinal injection.

Ninth and tenth days: One spinal drainage daily.

They likewise emphasize the danger of over-treatment; that after the first ten to fourteen days this may do positive harm. This has been the experience of most persons who have seen large numbers with this disease.

Litchfield,² reporting from Camp Grant, discusses ten cases of typical pneumococcus meningitis treated with the specific antipneumococcus serum of Kyes. Of these patients five died and five recovered. This mortality of 50 per cent of apparently proved up cases of pneumococcus meningitis is a most welcome step in a previously considered highly fatal disease.

Still further progress and recognition of specific antipneumococcus treatment is shown in a case report by Weaver¹⁹ of acute streptococcus meningitis with recovery. In this case antistreptococcus serum was used both intraspinally and intramuscularly. Weaver concludes that the improvement which followed each treatment with antistreptococcus serum was striking. In cases of streptococcus meningitis which are usually hopeless, the combined intraspinal and intramus-

cular administration of antistreptococcus serum would seem to be worth trying. The curative action of antistreptococcus serum depends largely on its opsonic content as does that of antimeningitic serum and the serum should "theoretically be useful in such a condition as meningitis in which it can be brought into direct contact with the bacteria."

Comment.—The conception that cerebrospinal meningitis is primarily a sepsis with secondary localization in the meninges is one of the valuable medical lessons learned from the war. Herrick's suggestion that the term "epidemic cerebrospinal meningitis" be abandoned for the more general "meningococcus infection" will receive wide approbation. Similar terminology in disease description has already come into use in such terms as streptococcus sepsis, pneumococcus infection, etc., as well the use of the more elastic terms pneumonitis and pleuritis in place of pneumonia and empyema.

From a practical therapeutic standpoint one would wish to call attention to the necessity of employing large amounts of serum when used intravenously not 2, 3 or 5 cc., but 60, 80 and 100 cc. daily, given slowly, warmed, well diluted, and with due regard to and precaution against anaphylactic phenomena.

COLLECTIVE ABSTRACT ON TUBERCULOSIS FOR THE YEAR 1918

BY JOHN B. HAWES, II, M.D., SECRETARY, TRUSTEES OF HOSPITALS FOR CONSUMPTIVES, BOSTON, MASS.

ANY review of the vast amount of literature dealing with such a subject as tuberculosis must at best be brief and incomplete. Furthermore, such a review must simply reflect the opinion of the person making such an abstract as to the relative importance of the various articles. I have attempted to mention here merely the more prominent articles that happened to appeal to me. I make no pretense that this review is in any way complete, and I tender my apologies to the various writers of important and valuable articles which happened to escape my notice.

Diagnosis

The standards of diagnosis prepared last year for the purposes of the Framingham Tuberculosis and Health Demonstration have proved of distinct value and have been in use all over this

country. Nothing particularly new in diagnosis, however, has been presented during the past year.

Slater¹ calls attention to the greater importance of the study of the history and symptoms as being of more value to the general practitioner than the physical and laboratory findings in the diagnosis of pulmonary tuberculosis. This article is full of sound common sense, and the points that he raises cannot be given too much emphasis.

Smith,² in a scholarly article describing the differential diagnosis, emphasizes particularly those cases of early hyperthyroidism as potential and frequent causes of error.

Meyer,³ from his experience with the complement fixation test, believes that a positive test indicates active tuberculosis, particularly when it has been positive two or three times after being repeated at intervals of one or two months. The complement fixation test, however, will hardly ever be of value to the general practitioner.

Heise and Sampson⁴ compare the findings by

¹ Litchfield, Lawrence: Pneumococcus Meningitis Treatment by a Specific Antipneumococcus Serum. *Jour. Am. Med. Assn.*, 1919, lxxii, 1345.

² Weaver, Geo. H.: A Case of Acute Streptococcus Meningitis with Recovery. *Jour. Am. Med. Assn.*, 1919, lxxii, 1362.

clinical examination with those shown by the x-ray, and are of the opinion that in the great majority of cases the x-ray reveals a lesion more extensive than that found by examination.

Holmes,⁵ in a thoroughly sound and conservative paper, states his opinion that the x-ray should be used more frequently than it now is to supplement the physical examination, but that it should never be used as the sole means of diagnosis. An opinion based on it alone has about the same value as an opinion based on physical findings alone. Without careful history both lose much of their value. Combined with other evidence, the x-ray may be of great value.

King⁶ calls attention to certain extrapulmonary sounds heard in auscultating the apices of young men. The sounds which he describes are undoubtedly motor joint crackles. This phenomenon has long been known as Perez's sign, and was carefully described some years ago by Ewart of London, and three years ago in an article by Hawes.

Hawes⁷ has encountered two types of diagnostic mistakes on the part of the general practitioner: first, those patients in whose lungs the sounds are vague, who are assured by their physicians on account of this that they have no tuberculosis, in spite of the fact that constitutional signs and symptoms are only too manifest; second, patients with acute and subacute pulmonary infections, of pneumococic or streptococic origin, who are diagnosed as tuberculous. In these cases he urges that the history and symptoms are of more importance than the local signs in the lungs, and that with proper care the correct diagnosis can be made.

Adelung⁸ has made a study of the incidence of syphilis as shown by a positive Wassermann reaction among consumptives in California. He apparently takes it for granted, however, that the presence of a positive Wassermann reaction means that the process in the patient's lungs is due to syphilis rather than to tuberculosis. This, of course, is very much open to doubt.

Corper,⁹ investigating the same subject, as a result of the routine blood examination of nearly 2,800 men and women residents of the City of Chicago Municipal Tuberculosis Sanitarium, found a definite, positive Wassermann reaction in 7.2 per cent of the men and 5.8 per cent of the women. This is approximately the same as the percentage found elsewhere in investigations.

Treatment

Nothing new in the treatment of tuberculosis has been offered. Curtin¹⁰ believes that the intravenous injection of iodoform, dissolved in

ether, has a remarkably curative effect, and Matsuda¹¹ reports some remarkable results in the use of Koga's cyanocuprol. These enthusiastic reports will need much further confirmation before they can be accepted.

Nonpulmonary Tuberculosis

A committee of which Dr. Arthur K. Stone of Boston was chairman,¹² has prepared some standards of diagnosis and treatment of tuberculous cervical adenitis. These standards represent an attempt to formulate some definite statements on which the diagnosis and treatment of this condition, which is so extremely common, are to be based. They are similar to the standards in diagnosis and treatment of pulmonary tuberculosis in adults and in children already prepared by a subcommittee of the National Association for use in the Framingham Health Experiment and Demonstration. These latter have proved of immense practical importance and value, and it is expected that these standards in the diagnosis and treatment of cervical adenitis will be equally valuable.

Davis,¹³ from his experience in private practice and in a London County Council school clinic in the treatment of tuberculous cervical adenitis, believes that the removal of tonsils, with suitable anti-tuberculosis treatment, results in the disappearance of the glands in many cases, but in the majority the glands themselves must be removed by operative procedures. He does not believe that tonsils should be removed, however, in every instance, or extirpation made, except after careful examination and selection.

Gauvain,¹⁴ discussing the treatment and training of nonpulmonary tuberculosis, chiefly tuberculosis of bones and joints, believes that tuberculous cripples should be treated conservatively but energetically for as long a period as possible and that treatment should be instituted soon after the onset of the disease. During this time their education, whenever possible, should be efficiently undertaken with special regard to their limitations and requirements. Even the most advanced cases may be very materially benefited. After-care and guidance should be systematically given. He believes that apart from philanthropic considerations the thorough treatment of these patients is not only logical but economically sound.

Schapira¹⁵ calls attention to the difficulty in the diagnosis of renal and genito-urinary tuberculosis. Tubercl bacilli are often found in the urine without subjective symptoms or apparent lesions. Tuberculosis of the bladder is frequent when there are no tubercle bacilli in the urine.

The bacilli are eliminated in showers. During the interval between these it is possible to get bacilli-free urine. Great care is needed in the diagnosis of tuberculosis of the kidney, in view of the fact that tubercle bacilli are often found in patients without tuberculous lesions or symptoms. The finding of a few tubercle bacilli from the urine of a certain kidney is not sufficient to condemn that organ.

Bugbee¹⁶ believes that nephrectomy is the only proper treatment of renal tuberculosis. He does not mention the use of tuberculin, nor does he speak of bilateral renal tuberculosis. No statement as to the treatment of renal tuberculosis can be considered a complete or up-to-date one unless the use of tuberculin before and after operation is mentioned.

Capell,¹⁷ discussing genito-urinary tuberculosis, emphasizes the fact that it is always secondary to tuberculosis elsewhere in the body. He believes that the real curative work in the treatment of such cases is not by the operation alone, but by hygienic measures and tuberculin, both before and after the operation. An early diagnosis is, of course, of prime importance. This article is full of sound common sense.

Tuberculosis in Children

Howell¹⁸ discusses the term "tuberculous infection" as distinguished from "tuberculous disease." He prefers to use the term "the primary lesion of tuberculosis" instead of "tuberculous infection." Following this, he discusses the diagnosis of bronchial gland tuberculosis. He believes that D'Espine's sign is an important diagnostic point. In treatment he emphasizes the fact that air need not be cold, and may be warm as long as it is fresh. Diet should be selected with a view of avoiding indigestion, especially fat indigestion from which such children are very liable to suffer. He advises against tuberculin treatment.

Hess¹⁹ points out that no provision is made for infants in the modern antituberculosis crusade, and believes that unless some such action is taken to care for infected infants, that our present campaign will fall short of its aims.

Bovine Tuberculosis

Marshall and Turner²⁰ recommend that the semi-annual subcutaneous testing of herds should not be continued, because too frequent tests lessen the sensibility of the animals to tuberculin. When a semi-annual test is required, the ophthalmic test only should be used.

Fleischner²¹ emphasizes the same point that a tuberculin test should be accepted only when performed by someone who, from training and ex-

perience, is qualified to decide. He believes that it is only by hard work and careful attention to details that bovine tuberculosis will ever be controlled.

Devine²² calls attention to the tremendous economic loss—over \$25,000,000 per year—to stock-keepers from bovine tuberculosis. He believes that the common wholesale method of condemning cattle because of a positive tuberculin test, performed by someone inexpert and poorly trained in its use, must be condemned. He believes that the tuberculin test is a most intricate one, and that to judge correctly from it as to whether or not a given animal should be condemned requires long and careful training.

Tuberculosis and Pregnancy

McSweeny and Wang²³ urge individualization in each instance in the solving of difficult problems presented by this combination. The Sea View Hospital in New York makes special provision for pregnant tuberculous women.

Norris and Landis²⁴ discuss at considerable length the question of pregnancy and tuberculosis. During the early months of pregnancy, pulmonary tuberculosis has little or no influence. Unless the disease becomes quiescent, however, tuberculous women should be advised against marriage, and, to a certain extent, against conception. Individual treatment is essential because no two cases are exactly alike. After the fifth month it is generally advisable to treat these patients expectantly, and to induce premature labor two weeks before time. Hygienic and dietary treatment should be employed in all cases.

The Discharged Sanatorium Patient

Lyman,²⁵ in a valuable article, discusses the importance of following up the discharged sanatorium patient. He describes in detail the system which has been adopted in Massachusetts by the Trustees of Hospitals for Consumptives of that State. He believes that the Massachusetts system is not only most likely to secure proper medical supervision for the discharged sanatorium patient, but is also calculated to insure a continued interest in the case on the part of the physician himself.

Billings and Hawes,²⁶ as a result of their study of over 1,000 patients discharged from the Massachusetts state sanatoriums during the two-year period from May, 1912, to May, 1914, conclude that sanatoriums are very much worth while. They believe that although early diagnosis is of prime importance, the fact that a patient is moderately advanced or advanced does not necessarily mean an unfavorable prognosis. It does not appear

that the incipient case is sufficiently impressed with the seriousness of his condition, nor that the patient discharged with the disease arrested or quiescent is made to realize how slim is his margin of safety. They believe that the words "sanatorium treatment in its broadest sense" should mean early diagnosis, length of stay of over six months, education of the patient and his family, and supervision of the patient after his discharge from an institution.

Johnson,²⁷ in discussing the treatment and after-care of the consumptive after leaving the sanatorium, calls attention to a very important point: that in dealing with consumptives, in the majority of cases we are dealing with substandard lives, whose efficiency in industry is below par. The real problem is to get the patient, after his discharge, into work where he can earn a living wage without suffering a relapse. In the after-care of the exsanatorium patient, three elements must be considered: housing and living conditions, suitable employment, medical supervision. He believes that if proper home conditions are available and treatment begun early, it makes no difference what sort of work discharged patients do under average conditions. There is much sound sense in what he says.

Thomson²⁸ discusses the value of limitation of sanatorium treatment. He believes that the value of the sanatorium for suitable cases is definitely established and cannot be replaced by other measures. It is useless to reproach sanatoriums for insufficient or unsatisfactory results when after-care is of equal, if not greater, importance.

Exercise and Work for Consumptives

Beyers,²⁹ discussing occupational treatment for the consumptive, believes that regulated work is highly beneficial, provided that the greatest care is exercised in the selection of the work and that the patient cooperates willingly. This latter factor is an important one. He states that even patients who are confined to bed seem to progress more rapidly when allowed to fill out part of the day with some interesting finger work instead of lying still and brooding over their lot. Contrary to expectation, relapses have numbered less than 2 per cent of the patients thus treated under his care. While such vocational training does not make a man a wage-earner in a new field, it has in many cases started new lines of thought regarding the life to be led after discharge, and has stimulated many patients to improve themselves and become more useful citizens.

Beyers' statements in this regard are of interest, when compared with the excellent work which is being done along this line by Colonel

Hoagland, in charge of the Army Tuberculosis Hospital in North Carolina. At this institution even the advanced bed cases are given some form of light occupational therapy, so far, at least, with good results.

McSweeney³⁰ discusses the same subject of exercise versus work for consumptives. He believes that absolute rest and idleness in tuberculosis tend toward the development of hypochondriasis and neurasthenia. He believes that in public sanatoriums the work done should be useful and economical from the institutional standpoint. As far as possible, work should be chosen in which the patient can engage after leaving the sanatorium. He states that there should be a rest stage, during which the patient should be studied and brought to normal condition, and that this rest stage seldom need exceed one month. The patient is then to be put on walking exercises of gradually increasing duration on a given course. This is continued until he can work.

Work As a Therapeutic Agent

There can be, of course, no discussion concerning the value of work as a therapeutic measure for suitable patients, but, in Massachusetts at least, it is extremely difficult to get suitable patients, and the ideal type of patient which Patterson describes, based on his experience at the Brompton Sanatorium in England, seems to be an exceedingly rare type in this country. McSweeney states that the preliminary period of rest need seldom exceed one month. If this is the average length of time which he has found necessary for his patients to rest, he is certainly to be congratulated on having a very remarkable group of patients sent to his institution.

Biggs³¹ describes the plan which has hitherto been somewhat in vogue, of having patients at a tuberculosis sanatorium do no work of any kind, but sit in the fresh air in reclining chairs by the hour, as one which will tend to "convert a self-respecting consumptive working man into a fairly healthy loafer." At the Municipal Sanatorium at Otisville, New York, each patient is expected to do some useful work, apparently with excellent results. The Board of Trustees of Hospitals for Consumptives, in charge of the four state sanatoriums of Massachusetts, with over 1,000 beds, nearly ten years ago made the regulation that "work for patients shall be regarded as a therapeutic measure and prescribed as such." The natural sequence of this work treatment is the farm colony, where the patient who is discharged from the sanatorium can go, for a period at least, before returning to his home.

Economic, Social, Administrative

Hawes³² presents certain answers to the question, "When does an individual become a case of tuberculosis from a board of health point of view, and when does he cease so to be?" from fourteen men prominent in tuberculosis work, and concludes as follows:

1. Every physician should report, and the board of health has a right to demand such a report, concerning every case of tuberculosis with bacilli recently demonstrated in the sputum.

2. In addition to this the physician should report every case in which he honestly believes the diagnosis of active pulmonary tuberculosis to be justified.

3. The board of health has a right to request, but not to demand according to law, information concerning every other case of tuberculosis in which the diagnosis is clear, even though tubercule bacilli cannot be demonstrated in the sputum, and even though there may not be marked signs of activity. The attitude of the board of health toward this last group of cases, which should be a large one, but which at present is a very small one, must be determined by the individual circumstances surrounding each case.

This question is one which confronts every health officer in the country dealing with tuberculosis. It would be of interest and value to have this matter discussed at length in various sections of the country, and obtain from such discussions a composite point of view.

Hawes³³ summarizes the factors in an idealized plan for controlling tuberculosis as follows: elimination of sources of infection, both human and bovine; education of the public, and particularly of children, in methods of right living and proper hygiene; early diagnosis of clinical tuberculous disease in adults and children; sanatorium treatment for the education and care of favorable and suitable cases; hospital treatment for the care and isolation of the advanced progressive cases; supervision of the tuberculous patient, before and after leaving an institution, and at all times if the patient does not, or cannot, have institutional care.

Hawes states that he is constantly unmaking diagnoses of consumption and trying to overcome harm done in this direction, while on the other hand too many cases of incipient pulmonary tuberculosis are still unrecognized. He believes that home treatment cannot, and should not, take the place of sanatorium treatment among the poorer classes, if the latter is in any way available.

Lyman,³⁴ discussing the control of the careless consumptive, makes a stirring plea for legislation to enforce compulsory segregation of the careless and incorrigible consumptive.

The *Bulletin of the New York State Department of Health*³⁵ calls attention to the progress that

New York is making in carrying out the statute which requires a tuberculosis hospital in every county having a population of over 35,000. The main features of the program for the State of New York are the establishment of adequate tuberculosis hospital provision for each county in the State, on the approximate basis of one bed for each annual death in such county. These county hospitals are to be inspected regularly, and it is hoped to make them the campaign centers of educational and medical work in each county. At the State sanatorium for incipient cases at Ray Brook it is planned to hold a course of instruction for superintendents and others. The county hospitals are likewise to have outpatient departments for patients, and physicians' clinics in cooperation with the health officers.

Armstrong,³⁶ describing the work of the so-called Framingham Experiment, financed to the extent of \$100,000 by the Metropolitan Life Insurance Company, defines this demonstration as a community method, successful or not, as events may prove, of disease prevention and health administration. Thus far the health experiment has apparently demonstrated the importance of sympathetic cooperation from local and outside agencies as a basis for social community control over disease-producing factors. It is hoped that further development will demonstrate that on a community basis, disease may be prevented and health created, thereby laying a permanent physical foundation for future social, economic, and spiritual evolution.

Ames³⁷ describes an interesting survey of Saranac Lake from the point of view of tuberculosis. Educational influences, emanating from nearby sanatoriums, and, locally, the "open door" for the tuberculous into unrestricted industrial and social activities, have done much to remove fear and ignorance and to create an intelligent public mind toward the disease. With this same attitude existent, the problems connected with the control of tuberculosis are becoming less and less difficult of solution.

Tuberculosis and War

Minor, Pratt, Brown, Stewart, McCrae,³⁸ and Bushnell, Elliott, Miller, Perkins,³⁹ discuss the general subject of the tuberculous soldier and tuberculosis and war. It is impossible to present the details or to review adequately these articles in a brief space. To those interested in this subject, these articles will offer valuable material. There is the same note running through them all, suggesting that the medical officers of all our armies were to a certain extent stampeded by tuberculosis, especially in the first year of the war.

According to the Illinois plan⁴⁰ for caring for the tuberculous soldier, an agreement has been reached between the State Department of Health, the State Tuberculosis Association, and the American Red Cross, under which the Red Cross will provide care for returned tuberculous soldiers in the interval between their return to their home communities and the time that more permanent provision is made for them, and will also provide one-third of the expense for their permanent care. An expert examination will be made by a physician representing the Illinois Tuberculosis Association. The remaining two-thirds of the cost of permanent care are to be provided for by local organizations and individuals through the State Tuberculosis Association.

The plan adopted in the State of Massachusetts is very similar to this. The Trustees of Hospitals for Consumptives, who are in charge of the four state sanatoriums providing one thousand beds, have an agreement with the local branch of the Red Cross to provide immediate treatment for any tuberculous soldier discharged from the army for this cause. The Red Cross in its turn guarantees to pay the expenses until a permanent arrangement can be made. So far this plan has worked out well. Soldiers who are still under the supervision of the Bureau of War Risk Insurance are likewise sent to state or local institutions and their expenses paid by funds from the Bureau War Risk Insurance.

Minor⁴¹ apparently believes that there is to be a great increase in the incidence and mortality of tuberculosis after the war. He urges wise legislation and philanthropy to combat this problem. So far, at least, we have no reason to apprehend any such increase in the incidence of tuberculosis.

Gafflikin,⁴² from his experience, believes army life is not a thing conducive to the cure of tuberculosis, but that it tends to bring about such infections, or at least to arouse them into activity. This he accounts for by the absence of rest. He believes that with a definite history of tuberculosis, even with no physical signs, the applicant should be rejected.

Tedeschi⁴³ calls attention to the similarity between certain cases of gassing and tuberculosis. It is important that this distinction should be made, as it undoubtedly accounts for many soldiers being classed unnecessarily as consumptives.

Comment is made⁴⁴ upon the great exaggeration in the amount of tuberculosis among soldiers, as based on a preliminary report. Colonel George E. Bushnell and others in a position to judge in this matter are right in protest-

ing against the unnecessary alarm regarding the prevalence of tuberculosis among soldiers in France and elsewhere.

Miscellaneous

Rathbun⁴⁵ discusses the incidence of tuberculosis among our immigrant population, and appeals for a reorganized and increased medical staff with equipment at each of the various immigration stations for a satisfactory minimum physical examination of each immigrant, and a sufficient number of tuberculosis specialists and trained roentgenologists to carry forward proper examinations for tuberculosis. He likewise urges an educational campaign to inform immigrant associations, steamship companies, and other institutions of advantages to be derived from the exclusion of tuberculosis aliens.

Duboff⁴⁶ concludes from his investigations that throat complications are no more frequent in tobacco users than in those who use no tobacco, and that tobacco does not predispose to laryngeal complications.

Webb⁴⁷ concludes likewise that the inhalation of the smoke of cigarettes does not aid in the outbreak of pulmonary tuberculosis.

Attention has been called to the distressing amount of tuberculosis among mine workers, marble polishers, and the like.⁴⁸ Unless there is a concerted move by employees and the community to control the conditions causing the disease, many more individuals must become affected as these industries continue to develop. He urges that the disease be made reportable and that legislation be introduced to control this evil.

Pierson⁴⁹ believes that a localized focus of tuberculosis, in itself insignificant, can be the cause of and may actually set up a localized or general asthma. This would account for many puzzling cases in which, in spite of a positive sputum, the distressing symptoms are due far more to the asthma than to the tuberculosis.

A CHILD FEEDING SURVEY

By Solomon Strauss, M.D., Chicago, Illinois

In the city of Chicago, excepting the public school medical service, there is no public agency concerning itself with the health, welfare and education of the little folks. The Infant Welfare Society of Chicago has for some years past undertaken "to keep babies well by advice, by supervision, by encouraging breast feeding, and by instruction of the mothers in the rules of hygiene"; by babies has been meant infants up to two years of age. At that age the Infant Welfare Society graduates them, not because the organization feels that the child is "finished so far as they are concerned," but because the number of welfare stations is not sufficient to take care of both infants and the older children and it was considered more important to care for the infants. This means that there has been no organization especially interested in the child from two to six, and as a result this child has come to the adult table and partaken of adult food regardless of his needs. How such a diet affects the child, especially in the congested districts of the city, records of children's dispensaries and of pediatricians best show. At the age of six the average child comes under the jurisdiction of the public school.

The Infant Welfare Society, feeling the injustice of turning away from its clinics children over two years old, undertook a food survey of the conditions and needs of the child between the ages of two and six. For a period of ten weeks clinics for children of this age were held at one of the Infant Welfare stations in a congested district. These clinics were planned and managed by an expert dietitian assisted by four student-teachers. A doctor and nurse were in attendance at each clinic. The neighborhood in which the experiment was carried out was chosen for two reasons: first, its general heterogeneous character; second, its high percentage of Jewish mothers, who, it had been reported, might prove more easily teachable because of their peculiarly close home ties.

The experiment was aimed to teach not only the family proper food values, but to give the student an actual opportunity to practise in the home the dietary rules of right living. It was attempted to educate the parent along the

lines of health through the paths of correct living and correct feeding. The student-teacher was enabled to apply her science practically to a most intense human problem and was given the privilege of studying and correcting at first hand home economics, often practised under anything but ideal conditions. If the cooperation of the mother was gained, the interest of the child held, then the survey would be a success.

The method of work in brief was as follows: Each student-teacher, under the personal direction of the instructor in dietetics, was placed in charge of one or more families for whom she was held responsible. The mothers with their two to six-year-old children came to the clinics once a week for individual and group instruction. At the first visit the children were weighed and measured and given a thorough physical examination by the physician and attendants. Cards giving the results of these examinations were carefully kept and studied by the physician and the dietary expert. The majority of the cases showed evidence of malnutrition, so that the work of the dietitian followed immediately that of the physician. The dietitian talked with the mothers individually and in small groups and also interested the mothers through the children.

A group of families to be visited in the homes was selected. Each student-teacher was placed in charge of a family. Her report was based on observations made at first hand in the home. Armed with her food-weighing scales, each student-teacher visited her family, spending the entire day in the home, carefully checked up all the food consumed by the children from two to six. After weighing or measuring food the exact scientific data were then obtained by calculation of the various food ingredients consumed as well as the caloric value of the food. Fifteen families in all were thus visited. Ignorance of food values alone was the prevailing condition responsible for poor nutrition in practically all cases, regardless of the extent or degree of poverty. In no case was shiftlessness found as a cause of poor feeding. In one instance the mother so wisely and well expended her very limited weekly food allowance that with the exception of additional milk, not the slightest suggestion could be made by the visitors. In addition to the calculations of food values made from study in the homes of the poor, at least two controls were carried out in families supposedly well able to handle the feeding of their children in a perfect manner. After the visits at the home, the parents received their subsequent instruction in proper feeding at the clinic.

Many devices were employed to attract and hold the interest of the child and the parent in properly cooperating in the experiment. Cards were kept on which were lists of foods to be avoided and foods to be used. When the child at clinic was able to report the proper amount of vegetable or cereal eaten, a little Brownie poster was inserted in the blank space in the child's card.

Since the survey is only now being completed, only a few results can be suggested.

First, tea and coffee drinking habits were most easily broken and, regardless of nationality, cooperation in this respect was immediately secured.

Second, whenever economically possible, a general willingness to add milk to the children's diet was found.

Third, great difficulty was experienced in obtaining the cooperation of the parents in urging children to take sufficient quantities and varieties of vegetables.

Fourth, equal difficulty was experienced in convincing the children of the necessity of going to bed early.

On the whole, the general attendance and the marked interest of both parents and children were satisfactory.

INFECTIOUS DISEASES OF CHILD IMMIGRANTS

In the steerage of vessels bearing immigrants to America disease often finds a breeding ground. Many have been the aliens sailing westward across the Atlantic who were borne ashore on a stretcher to the immigrant station at Ellis Island.

"It is impossible to imagine any more unfavorable conditions for recovery from measles," says a new government bulletin on "Infectious Diseases of Children," "than to be taken sick in the steerage in transit to the United States, and then, either in the height of the disease or before convalescence is well established, to be transported in overcrowded barges from the New York City docks to the immigrant station at Ellis Island."

"Besides the unfavorable sanitary conditions necessarily surrounding this procedure, the patient has almost invariably been exposed to the risk of cross infection before he reaches the hospital."

A study of 6,078 cases of infectious diseases among immigrant children is contained in *Public Health Bulletin* No. 95. Special reference is given to cross infection and hospital management.

During the years 1912 to 1916, inclusive, the records show that 6,078 children were admitted to the contagious disease hospital. These are considered in three groups. In the first group are those taken direct to the hospital on primary inspection, numbering 3,661. The second group includes the cases arising in the detention room where immigrants are held if the immigration authorities recommend investigation. The detention room, where overcrowding is a problem, sent 1,292 cases to the hospital. The third group consists of those who were taken to the general hospital for other diseases and while there exhibited symptoms of infectious disease. In this group were 917 cases.

The report eliminates 1,832 of the 6,078 cases, leaving only those patients admitted to the infectious disease hospital solely on account of contagious disease, exposure to contagion, or suspected exposure. The study deals with the fatality among patients so admitted, and their management in the hospital.

Measles was the most frequent in occurrence, there being 2,614 admissions. Scarlet fever admissions numbered 530 cases, chicken-pox 79; whooping cough 73; and diphtheria 70.

"From a study of 2,614 cases of measles occurring over a period of five years, together with a survey of literature," says the author of the bulletin, J. G. Wilson, "it seems that although both the incidence and case fatality of this disease are greatly influenced by age, there are other more important factors not yet understood which determine both the virulence and periodicity of epidemics."

From a study of the cases as they occurred at Ellis Island the following conclusions were drawn:

- Cross infection, especially that of diphtheria, was the most serious event that occurred in the course of measles.

- Broncho-pneumonia complicated 10 per cent of all the cases, being but little influenced by weather conditions in the frequency of its occurrence or its case fatality.

- The case fatality of measles complicated with broncho-pneumonia was 50 per cent, but it varied in an erratic manner and without marked relation to the total case fatality of measles.

- The incidence rate of broncho-pneumonia as a complication rather than its case fatality appeared to be an index to the severity of any particular outbreak.

- Proper isolation facilities greatly reduced the incidence of cross infections and complications and had a directly favorable influence upon prognosis.

- Suppurative otitis media, although the most frequent complication of measles, was not of grave prognostic import.

Broncho-pneumonia was the principal complication of over 60 per cent of the fatal cases of measles. The significance of this high percentage is not so much an indication that this class of complication should be regarded as necessarily fatal, it is stated, but rather, that it should be regarded as having been a determining factor in the severity of measles epidemics. The incidence of bronchopneumonia rather than the deaths thus complicated appears to have been the more important fact, since the percentage of fatality was subject to extreme fluctuations. The fatality from this complication averaged 50 per cent.

A concise summary of the principal groups of cases in which cross infection occurred is furnished. The bulletin contains the following comparative data:

The exact significance of the chief complications in fatal cases can be best appreciated when considered in relation to their frequency in non-fatal cases. Thus, from among 2,614 measles admissions for the five years, the following data are derived:

Broncho-pneumonia occurred 278 times with 141 deaths, giving a case fatality of 50 per cent.

Diphtheria occurred 44 times with 23 deaths, giving a case fatality of 52 per cent.

Scarlet fever occurred 53 times with 18 deaths, giving a case fatality of 34 per cent.

Whooping cough occurred 42 times with 6 deaths, giving a case fatality of 14 per cent.

Gastrointestinal complications occurred 92 times with 22 deaths, giving a case fatality of 24 per cent.

Suppurative otitis media occurred 481 times with 10 deaths, giving a case fatality of 2 per cent.

Nephritis occurred 18 times with 1 death, giving a case fatality of 5 per cent.

Inflammation of lymphatic glands occurred 17 times with 1 death, giving a case fatality of 6 per cent.

Bronchitis (not including the symptomatic bronchitis of measles) occurred 15 times with 1 death, giving a case fatality of 7 per cent.

Meningitis occurred 2 times with 2 deaths, giving a case fatality of 100 per cent.

Uncomplicated cases occurred 1,700 times with 5 deaths, giving a case fatality of 0.3 per cent.

Unlike measles the uncomplicated cases of scarlet fever formed the largest single group of deaths among the 530 admissions for scarlet fever. The most important complications in this class, with the resulting case fatality, are stated as follows:

Broncho-pneumonia occurred 27 times with 11 deaths, giving a case fatality of 40 per cent.

Measles occurred 42 times with 11 deaths, giving a case fatality of 26 per cent.

Diphtheria occurred 21 times with 9 deaths, giving a case fatality of 43 per cent.

Nephritis occurred 38 times with 2 deaths, giving a case fatality of 5 per cent.

Suppurative otitis media occurred 100 times with 1 death giving a case fatality of 1 per cent.

Parotid abscess occurred 2 times with no deaths.

There were 7 single and 1 double mastoid operations with no deaths.

"From the foregoing," writes Mr. Wilson, "it is evident that the chief danger was connected, first, with the virulence of the infection, which either suddenly overwhelmed the patient by its first onslaught; or, failing in this, so weakened him that a terminal bronchopneumonia proved a fatal ally; or, second, with the incidence of a cross-infection."

The somewhat startling suggestion is set forth that the immigrant population that clears through Ellis Island, coming as it does from all quarters of the world, forms a complex group that is continuously susceptible to measles rather than exhibiting periodicity in the prevalence of the disease, as seems to be true of fixed groups in communities where the transient element exists at a minimum.

The writer reviews the literature bearing on the recurrence of measles epidemics and cites the hypothesis of Crum and Müller that measles outbreaks in a given community either actually attacks or immunizes the whole susceptible population and that the off years following the epidemic simply represent the time required for a new susceptible generation to come into existence. He then seeks the application of the hypothesis to the study of measles cases at Ellis Island.

It is shown that the proportion of children to the total number of immigrants has borne an inconstant relation to the yearly variations in measles morbidity, thus indicating that the ratio of measles cases has a more direct relation to the whole body of immigrants than to some one section of them. The author then states his conclusions, as follows:

"A study of all the available data," he says, "simply establishes the fact that measles epidemics show a periodicity of recurrence, and that this periodicity seems to vary in different places. The underlying reason of this phenomenon has not yet been solved.

"There is only one factor which appears to bear a constant causal relation to epidemics of measles, and even this is incapable of explaining it in its entirety. This factor is overcrowding. Williams' showed very clearly how this influenced the situation at Ellis Island in the detention rooms, and the same problem was worked out by the health authorities in Glasgow, where both the incidence and the fatality of the disease were shown to bear a direct relation to the number of rooms occupied by the family.

"There can be no doubt that more success has heretofore actually attended home than hospital treatment, but it can be shown that when hospital conditions are changed so that isolation facilities are adequate, just as great success will attend this method of treatment. There have not yet been constructed any hospitals with absolutely adequate isolation facilities. By such hospitals are meant those in which it is never necessary to take any chances of patients directly infecting one another.

"This means that every child must be kept in isolation for a length of time that not only absolves it as a source of danger on account of the disease for which it has been treated, but also covers the incubation period of every contagious disease which it has not had.

"At Ellis Island Hospital there has been an effort to achieve this ideal, but so far it has not been reached. There has, however, been great improvement. A comparison of the years when isolation facilities have been decidedly inadequate with those when they have been considerably better, shews so marked an improvement in the results that one cannot help believing that it will eventually be entirely possible to eliminate every objection that may be raised to hospital treatment."

A brief resume of the data pertaining to scarlet fever, diphtheria, and whooping cough admissions will be found in the bulletin, as given below:

Scarlet Fever

The incidence of scarlet fever was greatest during the winter months.

The liability to the disease was greatest between the ages of 2 and 8 years.

The case fatality was highest in the second year of life.

After seven years of age the case fatality was practically the same for all ages.

Complications, though rendering convalescence slow, were not the usual cause of death.

The case fatality was determined chiefly by the virulence of the epidemic and the incidence of cross infection.

Diphtheria occurring in the course of scarlet fever more than doubled the liability to death.

The virulence of the infection varied greatly in different epidemics and to a less extent during the same epidemic.

The inference seems warranted that the majority of adults enjoy immunity to scarlet fever on account of a previous attack, whether recognized as such or not.

Diphtheria

Diphtheria was slightly more prevalent during the fall and winter than at other seasons of the year.

The case fatality was two to three times greater during the colder months.

The case fatality was highest during the first three years of life.

After eight years of age all cases recovered.

The high case fatality (25.7 per cent) was due chiefly to two factors—first, admissions late in the course of the disease, and, second, the tender age of the majority of the patients, nearly 70 per cent being less than eight years old.

The case fatality of diphtheria, when it occurred as a cross infection, was twice as high as when it occurred alone.

Diphtheria carriers were very prevalent in the Ellis Island population.

The diphtheria bacillus, once introduced into a general ward, spread rapidly from person to person, infecting three-fourths of all exposed in a period varying from twenty-four hours to six days.

About one-fourth of the persons exposed fail to become carriers, even after an intimate association of two weeks with those who have harbored the bacillus.

The majority of those whose throat or nasal mucus membranes afforded a suitable nidus for the growth of the diphtheria germ gave a positive culture after less than three days exposure to infection.

No cases with negative Schick test developed diphtheria.

Whooping Cough

The mortality from whooping cough was subject to marked variations.

The variable mortality depended chiefly upon, first, the incidence of cross infection as a complicating factor, and second, upon the age of the patient.

Deaths from whooping cough were all caused by some complication. Uncomplicated cases never proved fatal.

Specific vaccine treatment apparently had both prophylactic and curative value.

ILL EFFECTS FROM WEARING ARMY LEGGINGS

Assertions that the leggings and puttees worn by the men and officers of the United States army not infrequently cause discomfort for the wearer, and, in some instances, disability, have prompted a discussion of the question in the *Military Surgeon*.

Lieutenant Colonel James T. Rugh, M.C., who in one year examined the feet and legs of 30,000 officers and soldiers, who is the author of the article, points out that the clothing, either underwear, hosiery, or breeches and not the puttee or leggings may be the cause of trouble in many cases. Improperly adjusted lacings in the breeches, knots in lacing, tight garters, socks that turn over at the upper end, and tight breeches are often the factors that cause the discomfiture. If neglected, a serious constriction sometimes ensues.

Puttees which do not fit properly either cause soreness over the heel tendon where the lower edge rubs the shoe, or at the top in front. Unless the canvas legging is laced so tightly as to cause compression, it is not often a cause of trouble, except if the three layers of clothing beneath—the breeches, underwear, and sock—be improperly adjusted or wrinkled so as to produce constriction.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

INDUSTRY AND HUMANITY.* A study in Principles Underlying Industrial Reconstruction, with a chapter on "The Principles Underlying Health." By W. L. Mackenzie King, C.M.G., M.A., LLB., Fellow of the Royal Society of Canada, and formerly Minister of Labor of Canada.

A masterful mind has taken hold of the trouble-breeding world problems that manifest themselves in labor disputes, strikes, lock-outs, political misrule, injustice, poverty, sickness, and suffering, which have been resolved into their primary elements and analyzed as social forces by the process of clear thinking and reasoning. This has all been done before the book was written. The book is the finished work, a creditable volume presenting a broad doctrine of ethics and justice in industry.

The thesis of the book is stated as the Law of Peace, Work, and Health—an expression used by Pasteur, in 1888. At the outset this law requires a social environment that will in no way, either through accident, preventable disease, sickness, or injustice mitigate against the health, happiness, and well-being of the individual.

The author demands recognition by the men in control of affairs everywhere, both on the side of Capital and on the side of Labor, of the human aspect of industrial operations.

Says the author: "A new era in the progress of Industry and Nationality will begin, when, in all that begets strife and hatred in human relations, men come to see disorder and ferment akin to that evidenced by disease."

Antagonisms must be put aside for the larger considerations of human, individual, and collective benefit. The losses of life in industry from preventable causes, the preventable casualties of the shops and factory, the enemy diseases of an occupational sort, all of which exact a toll no less appalling than the more apparent loss of life in war, must be stopped. Human lives that are shattered by excessive nervous exhaustion, waste of energy, and occupational hazard must no longer be matters of individual concern. The whole problem, although it lies outside the borders of the science of economics, demands attention for purely economic reasons, besides the human aspect.

The studies around which the book is written were conducted at the invitation of the Rockefeller Foundation.

WORLD-POWER AND EVOLUTION.† By Ellsworth Huntington, Ph.D., Research Associate in Geography, Yale University. Author of "Civilization and Climate," etc. May be briefly described as the influence of climate upon human affairs. Includes an account of recent experiments in the production of a new species, and a new theory of same.

Professor Huntington's new book gives substance to a principle which the absence of facts and exact data have obscured in the past. The author demonstrates by sci-

entific methods that climatic conditions react upon health in a definite and measurable degree.

The book portrays the results of a study of 60,000,000 deaths of people in America, Europe, and Asia. Localities having closely similar weather conditions, with temperature and humidity the same have been grouped together for comparison with other groups in which differing climatic conditions exist. The death rate is regarded as a measure of the health of each group. Within each group a further comparison is made of the relation between the death rate from day to day and the changes occurring in the weather.

That climatic conditions, through their effect upon health, are largely responsible for differences of mental attitude both from place to place and from time to time, and with reference to evolutionary processes, is the thesis of this book. Business fluctuations are shown to correspond closely to fluctuations in the health of the people. Periods of financial depression and panic come closely upon the advent of abnormally high death rates, with the attending amount of sickness, while prosperous seasons go together with periods of improved health.

That climatic conditions largely determined the processes of evolution, the millennium of prehistoric time; that the production of new species, the development of human kind, and the progressive increase of mental power in man came about only after climatic changes had precipitated favorable conditions and environment, are propositions which the author advances. He presents a new theory of the changes that lead to the production of new species.

The book represents a great amount of original research and tedious clerical labor. The manner of presentation makes the work exceedingly interesting.

THE DOCTOR IN WAR.‡ By Woods Hutchinson, M.D. Cloth, 800, pp. 481, 29 illustrations.

Dr. Hutchinson's new book typifies the pride and love of the physician and surgeon for the profession that has done so much to rid warfare of its suffering and plagues. It is a book both entertaining and instructive, and yields its best when read in one's hours of leisure.

Witnessing the merciful, masterful labors of many hundreds of army surgeons, physicians, and nurses, who achieved unequalled triumphs in curative and preventive medicine and surgery in the hospitals of the British, French, Belgian, Italian, and American armies, has called forth the best descriptive ability of a versatile writer.

No attempt is made to present data of technical facts. Rather, the treatment of the subject expressed by the title is a descriptive and illuminative interpretation of the

Lessons in Sanitation Taught Us by the War

The recent war wrought radical improvements in American living methods. For one thing, it brought home to us, during the days when we were organizing and supporting a large army, the necessity for greater physical efficiency; for good habits, discipline, and, most important of all, cleanliness as an aid to good health.

The need for better sanitary conditions in camps, hospitals, amusement centers, industrial plants, on battle-ships, etc., was recognized and accepted.

We have a new national respect for sanitation—for strong manhood and womanhood.

Closer attention will be paid by all authorities to conditions in Schools, Factories, Hospitals, public buildings and private homes—and in no way can such conditions be improved more certainly than in a greater use of tile.

The need for public baths is felt in every community. Better toilets in public buildings—public comfort stations in greater number as a substitute for the "convenience" afforded by the disappearing saloon—improved conditions in all penal and eleemosynary institutions—better housing for the nation's army of working people. These are some of the pressing needs which tile will supply.

Pools, Baths, Toilets, Operating Rooms, etc., are more easily cleaned—keep clean longer—are more durable and therefore more economical—when tiled. Those who are concerned with such problems are urged to ask us for advice and counsel as to the proper methods for the installation and use of tile.

Domestic postage, \$3.00. Foreign postage, \$3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS. Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS. Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS. Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER. Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

BOOKS OF THE MONTH

(Continued from Page 184)

significant achievements of the army medical service. What it means to reduce an army's death rate from disease to a fraction of the death rate from battle casualties; what it means to the living generation to completely eliminate the typhoid plague from armies composed of millions of men; what it means to triumph over the infections of wounds that in other wars have proved so deadly; what it means to the world to establish huge army camps under sanitary supervision such that none of the cities of the world is as clean; what the import of these triumphs of medical science will be in the life of nations in the future, the author has suggested by a vivid portrayal of the army medical service in action.

The book will afford pleasure and satisfaction to the physician or surgeon who participated in the war. It will afford instruction and entertainment either to the professional man or layman.

HEALTH FIRST.* The Fine Art of Living. By Henry Dwight Chapin, M.D., professor of medicine, pediatric department, at the Post-Graduate Medical School and Hospital, New York City.

"Health First" is a book written by a physician who believes that in the coming decade the medical profession will be called upon more and more to devote themselves to social-industrial groups in their communities.

The author advises employers to interest themselves in the health and working conditions of their employees. He contends that the advantage to the worker in better protection against sickness and disease is likewise to the advantage of the employer, who profits by the increased efficiency of his workmen. A proper estimate of the value of good health, he believes, is fundamentally important to the individual, and should have the moral reinforcement of the employer's interest in the individual's health.

The book is not addressed exclusively to the employer, however. It contains practical counsel in matters of health for old and young. From the cradle to old age it portrays step by step the every-day physiological health precautions and the dangers to health. In no place is the author technical in his manner of expression.

"Health First" is a volume which social groups, lodges, fraternal organizations, and employers might profitably distribute among the personnel of their organizations. They could expect in return an increased vigor, longevity, and greater productivity, because this book has in its pages that which will cause many to aspire for health in greater abundance. The chapters relate to intimate topics of personal habit.

PATHOLOGICAL TECHNIQUE.† A practical manual for workers in pathological histology and bacteriology, including directions for the performance of autopsies and for clinical diagnosis by laboratory methods. By F. B. Mallory, M.D., associate professor of pathology, Harvard Medical School; and J. B. Wright, M.D., pathologist to the Massachusetts General Hospital. Seventh edition, revised and enlarged.

There is probably no other one book which is as useful in a pathological laboratory as Mallory's and Wright's Pathological Technique. Its clearness and simplicity make it useful for the busy practitioner doing his own laboratory work, and its completeness and accuracy, espe-

Chlorazene used as a gargle

Chlorazene used for wounds

Chlorazene used as a douche

DR. WM. McNALLY, Chemist to the Coroner of Cook County, Illinois, reports 781 recorded deaths due to Phenol and 110 deaths due to Mercuric Chloride in Cook County, during the years 1905 to 1917, inclusive. Many of these deaths were accidental.

Accidents are made impossible by the use of CHLORAZENE, Dakin's water-soluble, non-poisonous antiseptic, FIFTY TIMES stronger in its germicidal action than Phenol. CHLORAZENE is non-irritating, safe and stable. For these reasons, it is fast becoming the universal antiseptic.

CHLORAZENE solution is used with excellent results as a gargle in sore throat, mouth and nose infections and as a prophylactic.

CHLORAZENE is also successfully used in surgery, eye infections, wounds, burns, as a vaginal douche and as a powerful, effective antiseptic for general use.

Solutions are quickly and conveniently made by simply dissolving CHLORAZENE Tablets or Powder in a glass of water.

For Sale at All Druggists—Specify "Abbott's"

Chlorazene Tablets in bottles of 100, 500 and 1000. Chlorazene Powder in hospital packages No. 1 and No. 2. Chlorazene Cream, Chlorazene Surgical Powder, Chlorazene Surgical Gauze.

Prof. Anderson

Blasts Every Food Cell in Whole Wheat and Rice

Prof. A. P. Anderson, formerly of Columbia University, solved the problem of steam exploding ALL the food cells in whole grain. The best other forms of cooking, baking or toasting fail to do that.

He seals the grains in guns, and revolves the guns for sixty minutes in 550 degrees of heat. Thus the moisture in each food cell is changed to steam.

When the guns are shot the steam explodes. In every kernel occur over 100 million explosions—one for every food cell.

The grains come out in bubble form, eight times normal size. They are thin, flaky, toasted tidbits with a nut-like taste. With cream and sugar or in bowls of milk they are veritable food confections.

The result of this process is easy, complete digestion. Whole grains are made inviting. Thousands of physicians, in many conditions, now advise this form of grain food.

BOOKS OF THE MONTH

(Continued From Page 22)

cially in the preparation of stains and the methods of staining tissues, render it invaluable as a book of reference in the pathological laboratory. The seventh edition, like those which have gone before, deals in great detail with bacteriological methods, the preparation of culture media, and contains a very usable description of pathogenic bacteria and fungi with their cultivation and differential diagnosis. There is a short section on animal parasites, the clinical pathology of blood and serous fluids, including the Wassermann reaction, and, finally, an excellent description is given of the technique to be used in postmortem examinations. The additions to the sixth edition of 1915 include the classification of pneumococci according to the Rockefeller methods, a few media for the differential diagnosis of bacteria of the colon typhoid group, the Fontana method for staining the *Theponema pallidum* in smears, and the newer methods of differentiating types of leukemia by the oxydase reaction. These additions bring the book fully up to date and make it more than ever one which even the smallest laboratory should have.

RADIO-DIAGNOSIS OF PLEURO-PULMONARY AFFECTIONS.* By F. Barjon: Translated by James A. Honeij, M.D., assistant professor of medicine in charge of radiography, Yale Medical School, New Haven, Conn.

Dr. Honeij is to be congratulated upon his excellent translation of Barjon's work on the x-ray, and the medical profession in this country, at least that part of it which deals with diseases of the lungs, is likewise similarly to be congratulated upon having such excellent work at its disposal. Not only is the print clear and legible, the book itself of a convenient size and weight, and the photographs of the highest order of excellence, but there is also running through it a vein of conservatism and modesty which is exceedingly rare in the majority of x-ray treatises. It would appear, to the reviewer at least, that many x-ray enthusiasts would do away or endeavor to do away with the clinician or clinical methods.

The tone of this book is, however, quite different as shown by the following on page 117:

It is not to be assumed that the radiological diagnosis of tuberculosis is to displace clinical examination and auscultation. Radiological examination may often be useful, but may often give no indication. It is not infallible. Certain light, disseminated lesions, insufficient to change the density or the elasticity of the parenchyma, may perfectly well pass unnoticed. The radiologist, when not taking into account clinical methods of examination, may very well declare a case of incipient tuberculosis with apparent signs of auscultation to be non-tuberculous. But the same is true of the physician who has relied wholly on clinical methods.

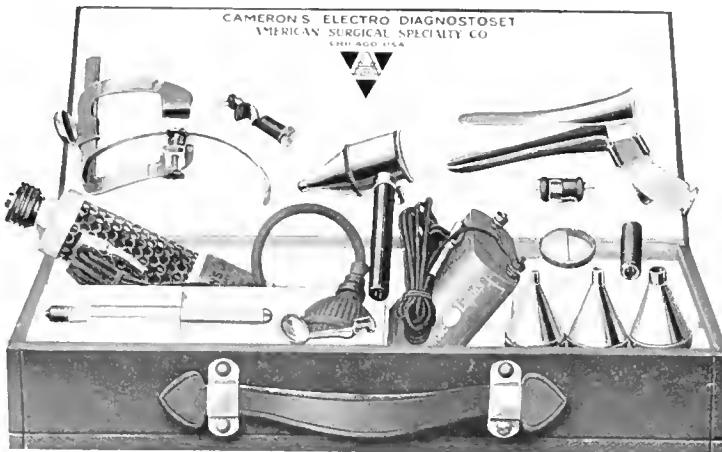

That the author is a firm believer in the value of the x-ray, however, is shown in many ways, for instance:

The time is coming when the information furnished by radiological examination will be as indispensable as that obtained by means of the stethoscope. * * * * * (Page xvii): At once the superiority of this method supersedes all others, for palpation and auscultation give information only as to the condition of those organs which are close to the thoracic wall; auscultation reveals only lesions superficial enough to transmit to the ear perceptible sounds, while the eye can observe lesions that are concealed in the deeper tissues.

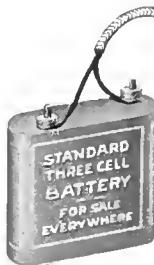

In the initial chapter, methods of examination of the normal chest are considered. He then takes up the subjects of pleurisy and circumscribed and encysted pleurisy.

Improved Instrumentation—Perfect Illumination CAMERON'S ELECTRO-DIAGNOSTOSET

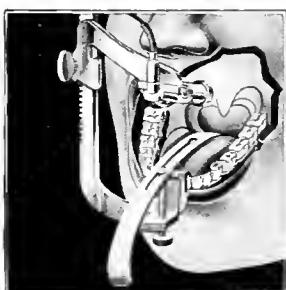

combines electrically lighted instruments for orificial examinations, each instrument being specifically designed to insure accurate diagnosis and to simplify surgical technique.

The instruments are original in design and simple in operation, and represent the latest developments of surgical experience.

Awkward, interfering, uncertain light adjustment by assistants is done away with when Cameron's Electro-Diagnoset is used, whether in the office, hospital, school or home.

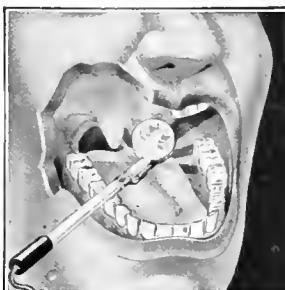

An abundance of clean, cool, direct white light is afforded for eye, ear, nose, throat and vaginal examinations and treatments, and for transilluminating frontal and maxillary sinuses etc. The body tissues are shown in their actual color and condition.

The light is operated on both battery and city current. Our Standard Potential Reductor Unit is for either alternating or direct current, 100-130 Volts. Supplied in 220 Volts if specified. Batteries, standard 3-cell, obtainable anywhere. These batteries will never short circuit, for they have no spring contacts. Renewal bulbs are ordinary inexpensive flashlight lamps.

The Electro-Tonsillassistant

For oral surgery and treatments. The automatic tongue depressor holds tongue well forward and upward while lamp positioned in the palatal arch (out of the field of operation) furnishes direct, unfailing light throughout the entire mouth and throat. Mouth gag is automatically adjustable and cannot slip. In tonsilectomy, adenectomy, etc., it gives operator maximum of room, plenty of light, and two free hands. Light cannot be dimmed by blood or mucus, or accidentally broken. All parts readily sterilized.

The Diagnostolite

A small white sanitary Opalite tube into which is fused a lens for concentration light rays (the searchlight principle). Useful for all oral examinations, in deep abdominal wounds, transillumination of nasal regions, maxillary and frontal sinuses, etc. The detachable laryngoscopic mirror is for diagnosis of post-nasal region, vocal cords, dental process, etc. The double vacuum construction (like a Thermos bottle) assures coolness, is clean and prevents electric shock. A better lamp for surgical use can never be made.

The Diagnostoscope

For aural and nasal examinations. Gives clear, magnified view of Tympanum without shadows or reflections. Includes both operating and diagnostic lenses, three ear and one nasal specula and pneumatic bulb for aspiration and massage.

Particular attention is directed to the shape of the aural specula, which are designed to project the light beyond the apex of the attachments and in this way clearly illuminate the ear drum.

The Vaginalite

A vaginal speculum electrically lighted. Gives abundant evenly diffused light throughout entire vaginal area. Light is never in way of operator. In Uterine Hemorrhage, Tamponments, urethral treatments, Urethral Treatments, etc., it does away with uncertainties and is a positive aid to better results. This instrument is entirely free from springs and set screws, is of medium size, is self-retaining, and is adaptable for an illuminated Simms modification.

Ethyl Chloride (Gebauer's) Local and General Anesthesia

The most improved and economical tube for the administration of Ethyl Chloride on the market.

The most economical: Because it sprays the liquid in the form of a vaporized stream, thereby hastening evaporation and consequent anesthesia, using 1-10 the liquid used by other tubes. Because the ethyl chloride is put up in a metal tube that will not leak or clog and the liquid is guaranteed to maintain its purity indefinitely.

40 grm tube with ordinary spraying nozzle, \$1.10
80 " " " " " " " " 1.75

Flexible spraying nozzle alone, - - - - .50
Graduated dropper, - - - - .50

The flexible nozzle and the graduated dropper will fit either size tube and can be used indefinitely.

BOOKS OF THE MONTH

(Continued From Page 24)

He frankly admits that in many pleuritic processes radioscopy is of comparatively little value. As an adjunct to the use of artificial pneumothorax, however, x-ray examination both before and during treatment is indispensable. He urges that radiologists learn to discuss the interpretation of abnormal shadows of the hilus region, which might almost be called the area of romance in the chest.

In his chapter on the enlargement of the tracheobronchial gland, he admits that in adults such enlargement is often due to perfectly innocent infection. In children, however, he believes that tuberculosis is the most common cause. His chapter on the acute infectious pulmonary processes, particularly abscesses and gangrene, is of great value. In tuberculosis of the lungs, he believes that not only is an x-ray examination of value in diagnosis, but that it is also important in following the progress of the individual patient. He admits, however, that in incipient tuberculosis, clinical examination, history, and auscultation signs and symptoms are of more importance than the x-ray.

On the whole, this book is an excellent one and a valuable contribution to our literature in this subject.

EQUILIBRIUM AND VERTIGO.* By Isaac H. Jones, M.A., M.D., laryngologist, Philadelphia General Hospital, etc. With an analysis of pathologic cases, by Lewis Fisher, M.D., laryngologist and otologist, Mt. Sinai Hospital, Philadelphia, Pa.

Medical officers returning from military duty with the Aviation Section of the Army are thoroughly acquainted with this work, which has been adopted as the standard by the Surgeon General's office for the examination of flying men. Its value in this field, its inestimable value in the saving of human life and government material, has impressed all otologists on duty with Aviation Boards.

The book, which is the product of years of work by Jones and his colleagues, is primarily a general non-military work, with a wide scope of interest to the general practitioner, surgeon, ophthalmologist, neurologist, syphilographer, and, of course, the otologist.

Part I discusses in separate chapters the relation of the internal ear to these branches of medicine, and gives in each a practical working basis for the study of the kinetic-static sense with the new turning, past-pointing, and falling tests, together with their value as diagnostic aids in the field of medicine.

Part II takes up the study of the internal ear from the neuro-otological standpoint; and, by clearly arranged text, gives a clear and concise exposition of those facts regarding nystagmus and the labyrinth which in hitherto published works have served to puzzle the majority of readers.

The closing chapters deal with practical and pathological considerations of the study, with hypothetical cases, and finally an analysis of a number of pathological cases.

The book is splendidly put together and is replete with instructive illustrations and diagrams.

Spreading the Gospel of Sound, Restful Sleep—

The co-operation being given the medical profession by Public Health Officials, Nurses and Welfare Workers everywhere, in spreading the Gospel of personal, household and civil hygiene, sanitation, health and efficiency is already accomplishing great things.

The work is worthy and deserving of generous support. "What the Leading Medical Journals and Health Magazines say about Separate Beds and Sound Sleep"—a booklet which reflects the latest authoritative thought on the all-important subject of sleep as a contributing factor to human health and efficiency—is this Company's most recent contribution to the Cause.

We shall be glad to send a supply of these booklets in any quantity for general distribution, to any Physician, Public Health Official, Nurse or Welfare Worker, upon request.

BOOKS OF THE MONTH

(Continued From Page 26)

chooses of war. It is essentially an abstract of three critical reviews by K. Birnbaum, of Berlin, which appeared in the *Zeitschrift für die Gesamte Neurologie und Psychiatrie* in 1915 and 1916, based upon 360 separate articles. The authors take Birnbaum to task for not giving separate attention among the psychoses of war to mental confusion previously recognized in Germany under the names of *Amentia* and *Verwirrtheit*, but Birnbaum refuses to separate it from hysteria. Although the original German articles soon will become available in this country, those who read French will prefer this excellent résumé, which has the added feature of being interspersed with the comments of the French authors, who naturally take delight in calling attention to the views of the war neuroses which have crystallized in their own country, the superior clarity of which they are certain will appeal to the unbiased reader.

NOTICES OF BOOKS RECEIVED

[*Notices of Books Received* will be found on advertising pages 36 and 38.]

IN THE HEALTH BULLETINS

Illinois Health News, in the March booklet, prints several papers on the subject of the proposed housing code in Illinois.

The January-February *Bulletin of the State Health Department of Minnesota* is devoted to the subject of rural methods of waste disposal.

The *Bulletin of the Milwaukee Department of Health* for February contains brief, crisp articles on the leading subjects of disease prevention.

A list of the literature distributed by the Minnesota Public Health Association is contained in the *Minnesota Health Journal*, April 10, 1919.

The text of the Local Health Reorganization Bill for the state of Ohio and other legislation pending and passed in the Ohio Legislature, may be found in the February issue of the *Ohio Public Health Journal*.

Florida Health Notes, the official bulletin of the State Board of Health of Florida, publishes in the February number the Report of the American Public Health Association on the subject of influenza.

Public Health, the monthly journal of the Michigan State Board of Health, is entirely devoted in the March issue to the subject of nursing; an excellent collection of articles covering fifty pages is given.

S. Dana Hubbard, M.D., superintendent of industrial hygiene, New York City, is the author of a discussion on "Occupational Affections of the Skin," appearing in the *Monthly Bulletin* of the Department of Health of the City of New York, February number.

The February issue of the *Public Health News* of the Department of Health of the State of New Jersey, contains an article on "Some Observations on the Recent Epidemic of Influenza" by Martin G. Synnott, of Montclair, N. J., and discusses the relation of the state to child welfare work.

Public Health Reports, of May 16, 1919, contains a paper by Sir Arthur Newsholme, K.C.B., chief medical advisor of the Local Government Board of England, on the subject, "Work of Red Cross Organizations in Relation to the Preventive Medicine of the Future." The paper was read at a meeting of the American Red Cross at Washington, D. C., May 2nd.

HYCLORITE

Concentrated Sodium Hypochlorite

For Office Practice and Hospital Surgery

A sodium hypochlorite solution of standardized hypochlorite strength and alkalinity for irrigating, dressing or swabbing infected cases. Upon the addition of prescribed proportions of water the solution is immediately ready for use without further manipulation or chemical titration.

It Is More Than an Antiseptic

Cleans and Deodorizes Infected Wounds. Hyclorite cleans the wound by dissolving and removing necrosed tissue, pus and blood and plasma clots, yet without precipitating protein of the lymph exudate or inhibiting leukocytosis, phagocytosis or the digestive action of tryptic enzymes. In this respect Hyclorite is decidedly superior to antiseptics of the chloramin and dichloramin type which have been shown to possess no solvent or cleansing action.

Makes a Dakin's Solution in one minute. By merely adding water to Hyclorite a Dakin's solution of the correct hypochlorite strength and alkalinity is made without waiting, filtering, titrating or adding other chemicals. *Always ready for use in emergencies.*

Less Irritating than Dakin's solution made by other methods. Hyclorite is decidedly less irritating than Dakin's solution made in the usual way because the alkalinity of Hyclorite is different in quality and quantity. The alkalinity of Hyclorite is tested in our laboratories to correctness by the *Hydroxyl-ion-concentration* method, the most accurate test known.

Keeping Quality. Unlike other hypochlorites which lose their strength rapidly and must first be tested before use, Hyclorite retains its strength practically unimpaired for long periods.

Effective in High Dilution. Hyclorite is also employed with noteworthy success in dilution of 1:200 for wet dressing, and 1:1000 for irrigation. In badly necrosed cases topical application of *undiluted* Hyclorite has proved remarkably effective.

DEFINES SCOPE OF INDUSTRIAL PHYSIOLOGY

The placing of industry on a scientific foundation so that the causes of accidents and sickness and dangers to the health of workers will be removed, will be accomplished in large part by the study and application of the science of industrial physiology, so termed by Frederick C. Lee, professor of physiology in Columbia University, consulting physiologist to the United States Public Health Service, and chairman of the Committee on Fatigue in Industrial Pursuits of the National Research Council, according to an article by Professor Lee. He has written an excellent, concise review of "some of the topics that have been or are being investigated, and some of the results." The paper appears in *Public Health Reports*, April 11, 1919, under the title, "The New Science of Industrial Physiology." Following are a few paragraphs selected from the review:

"Certain physiological and psychological tests have been employed with workers, and it appears practicable to employ some of these tests in selecting workers and assigning them to their jobs.

"The output of the successive hours of the working day in different types of operations has been measured, and the daily curves of the output have been plotted. These vary with the kind of operation, but are alike in showing a reduced efficiency, indicating a growing fatigue, as the day proceeds.

"Reduction in the length of the working day is characterized by an increase in the output of the successive hours and usually by a total increase in that of the day. The optimum duration of work probably varies with the character of the work itself.

"The introduction of resting periods in the working spell is accompanied, especially where the working day is long, by a total increase in the day's production. A five-hour working spell, unbroken by resting periods, is probably always too long.

"Overtime following a day of labor is inadvisable, as is also Sunday work following a week's labor. These tend to impair the working power of the worker.

"A hot day tends to impair strength and reduce output. Every effort should be made to keep the body of the worker cool.

"Night work is, in general, less efficient than day work. Its total output is less, and this, with a long working night, falls off enormously in the early morning hours. Alternation of periods of night work with periods of day work is more profitable than continuous night work.

"Women are capable of performing a much greater variety of industrial operations than has heretofore been recognized. They should not be employed for night work. Statistics show that they are absent from their work much more frequently than men. The problem of women as compared with men in industry is not that of their greater or less general efficiency, but rather a problem of what types of work each sex is best suited for.

"Accidents to workers are a grave source of inefficiency. They are caused by fatigue, inexperience, speed of working, insufficient lighting, high temperature, and other factors. Many industrial accidents are preventable, and adequate provisions for first-aid measures tend to diminish the seriousness of accidents.

"Food and efficiency are directly connected with one another, and suitable and adequate food can probably be best provided through the establishment of industrial canteens.

"A high labor turnover is incompatible with the highest degree of efficiency. It is expensive, in that it imposes upon the employer the necessity of training new workers, and it is a serious factor in the causation of accidents.

"Physiological analyses of certain operations have been made, by means of the cinematograph and other methods, and it has been found possible to eliminate unnecessary motions and to train workers so as to secure a more regular rhythm, such measures increasing efficiency."

SCIENTIFIC—EFFICIENT ECONOMICAL *Pain Relieving Methods*

You appreciate the value of sunlight as a therapeutic agency; you know about the pure white rays, the violet rays and the ruby screen. The Sterling Therapeutic Lamp combines all these agencies in an efficient and economical manner.

STERLING THERAPEUTIC LAMP *"The Light That Heals"*

Has proved one of the most efficient methods of relieving pains; its effect is soothing and analgesic; its rays are germicidal. The warm, soothing, soft rays penetrate and vitalize every cell and tissue, new cell growth is stimulated; the body is refreshed and vitalized.

In rheumatism, neuralgia, neuritis, lumbago, in nervous conditions and a score of other symptoms and diseases, including skin and scalp disease, the Sterling Therapeutic Lamp is invaluable for the relief from pain, inflammation and for corrective purposes.

Widely used in sanitariums, physicians' offices and hospitals; special sizes are adapted for the use of patients under the supervision and direction of the family physician.

Write for our interesting Illustrated Booklet showing the various sizes and uses of the Sterling Therapeutic Lamp.

City

Fix Date of Tuberculosis Meeting

The dates for the Mississippi Valley Tuberculosis Conference, which will meet in Des Moines, Ia., have been set for September 23, 24 and 25. The officers for the Conference this year are Sherman C. Kingsley, of Cleveland, Ohio, president, and Ralph Reed, of Des Moines, secretary.

England O. K.'s Fatigue Research Board

The studies of working conditions in the industrial establishments of England respecting the hours of labor, methods of work, health of workers, and relative production of fatigue, begun by the Health of Munitions Workers Committee in 1917 and 1918, will be continued by a new government Board, known as the Industrial Fatigue Research Board. The new body is under the joint control of the Department of Scientific and Industrial Research, and the Medical Research Committee.

JOURNAL OF DENTAL RESEARCH

The first issue of a new quarterly periodical, the *Journal of Dental Research*, is now in preparation. The names represented on the editorial staff and among the contributors give substantial worth to the magazine. It will devote its pages to research in the science of stomatology, and will publish the proceedings of dental and stomatological societies. The journal will be supported in part by contributions for the purpose, and in part by a cumulative endowment fund. It continues the former *Journal of the Allied Dental Societies*. The editorial office is located at the office of the College of Physicians and Surgeons, Columbia University, 437 West Fifty-ninth Street, New York City.

BUREAU DEVISES SIMPLE RESPIRATOR

An improvised or home-made respirator for protection against dust, which can be supplied at little expense to workmen who are exposed to dust from the materials of their work, has been devised by the Bureau of Inspection of the New York Industrial Commission. Tests have been made of the various types of respirators. It is stated in a booklet issued by the State Department of Labor of New York, describing the appliance, that dust may be filtered out of the atmosphere effectively for four hours by the use of one-half ounce of clean, absorbent cotton, fastened to a strip of cheese cloth or closely woven muslin, five inches wide, and of sufficient length to tie about the head. It should cover the nose and mouth.

HEALTH OFFICERS' ANNUAL MEETING

National and state programs in public health and their proper reciprocal relationship, subjects which define the scope of discussion at the thirty-fourth annual meeting of the Conference of State and Provincial Health Authorities of North America, describe the symposium of the program announced by the Conference for the two-day session at Atlantic City, N. J., June 6 and 7.

Six papers are included in the program, among them being three on the subject of health insurance.

The speakers will include Dr. Frank A. Goodnow, president of Johns Hopkins University; Allan J. McLaughlin, M.D., assistant Surgeon General, United States Public Health Service; Livingston Farrand, M.D., chairman, American Red Cross; John A. Andrews, secretary, American Association for Labor Legislation; George E. Tucker, M.D., Aetna Life Insurance Company; and John A. Lapp, managing editor of MODERN MEDICINE.

AMERICAN

THE PRODUCT OF SPECIALISTS

SERVICE

STERILIZERS—DISINFECTORS

EXCLUSIVELY

"Base Hospital A. E. F.
Somewhere in France.

March 25, 1919.
American Sterilizer Company
Erie, Pennsylvania.

Gentlemen:

The enclosed small Photo is being sent to you for whatever interest it might hold.

Of course, it is not news to you that the "AMERICAN" has been used extensively across the sea, both now and during the time the war was in full progress, but this particular snapshot is sent to you merely to portray the apparent pride which these

"soldiers" display in standing before their mechanical pet, just as the proud owner of an automobile at home might do. The two warriors pictured are Annamites, natives of one of the

French colonies, and were brought from their far away homes in Asia to "do their bit," While not fitted for combatant duty, they were militarized, and acted in the same capacity as our U. S. labor battalions. However, they took their duties very seriously and bedecked themselves in all sorts of cast-off uniforms--French, American and others too nondescript to classify. A picturesque lot, they afforded much amusement to the American soldiers on duty and patients at the immense hospital at * * * *, where the picture was taken. Now they have all been sent home again (how I envy them), and will doubtless relate to their wide-eyed and wondering folks at home--at least these two--how a poor soldier's uniform, fresh from the Front, would be cooly and deftly thrust into this mysterious monster, to emerge somewhat physically changed, to be sure, but transformed again for a now confiding user. This statement, of course, is not necessarily made from personal experience, but it was always comforting to know that if "company" should unexpectedly arrive, there was a way out of the difficulty, and the "Cootie Chaser" was, therefore, always kept in good trim, with a goodly pressure of steam.

Assuring you that you played an active and important part in the "Big Fuss" over here, I am

Respectfully yours,

Signed * * * Sergeant."

The above is but one of many commendatory letters we have received telling of "AMERICAN" sterilizers and disinfectors in use at home and abroad.

That "AMERICAN" apparatus, with such a record of extensive and exceptional service, was able to meet the exacting wartime requirements is your best assurance that they will give you complete satisfaction.

May we help you with your sterilizing and disinfecting problems?

ERIE, PENNSYLVANIA

Lunchroom—Wilson and Co.

Make It Your "First Aid"

You recognize, of course, the great value of a warm, wholesome, nourishing noon lunch as a builder of reserve energy; why not do what thousands of other "guardians of health" are doing in industrial plants, schools and large retail establishments, making the lunchroom their "first aid" as a builder of loyalty, satisfaction and greater efficiency.

VITROLITE TABLE TOPS

are notable for their widespread use. There are reasons—they are the definition of whiteness itself, crystal smooth, with a flinty hard surface that defies all stains and food acids. They can be cleaned in a jiffy with a damp cloth. They save all table covers and the expense of laundering. They last a life time.

*Interesting data is yours
for the asking*

The Vitrolite Company
620 Chamber of Commerce Bldg.,

A Million Industrial Accidents

Between the dates of June 30, 1914, and June 30, 1918, a total of 1,099,053 industrial accidents were reported in the State of New York under the workmen's compensation law. The number of cases in which compensation was paid for disability, or is now being paid, is placed at 201,786 in reports compiled by the New York State Industrial Commission. There were 5,252 deaths out of the million and ninety-nine thousand accident cases.

Harvard Offers Summer Course

The Harvard Graduate School of Medicine has announced a summer course in physical diagnosis to be given at the Massachusetts General Hospital, Boston, Mass., during July, under the direction of Professor Richard C. Cabot, A.B., M.D. He will be assisted by Professor Lesley H. Spooner, M.D. The course will include studies and demonstrations in the examination of patients, clinical lectures and demonstrations, laboratory exercises, and autopsies and visits to other institutions.

Establish Contact Between Physicians and State

The county medical societies of Illinois are assisting the state health authorities in organizing a relay health service between state and counties, says the *Illinois Medical Journal*. The county societies designate one or more of the members as "collaborating health officers," whose task is to maintain contact with the state health officers and to keep the local society informed of current events in public health matters. They procure and distribute information upon new health legislation, new and approved procedure in preventive medicine and hygiene, and supply the state health department with information regarding local health problems.

DISPOSAL OF INDUSTRIAL WASTES

Public Health Bulletin No. 97, on the subject of "The Treatment and Disposal of Industrial Wastes," is being distributed under the direction of the Surgeon General. It contains a resumé of the data collected during 1915 and 1916 in a testing plant for the treatment and disposal of strawboard wastes.

A second treatise concerns "The Determination of Biochemical Oxygen Demand of Industrial Wastes and Sewage," prepared by Emery J. Theriault and Harry B. Hommon. The method employed has been modified to give consistent and accurate results with sewage and a variety of industrial wastes, such as those produced by tanneries, strawboard mills, breweries, distilleries, canning establishments, dairies, abattoirs, and similar plants, as well as highly purified effluents.

The experiments in the treatment of strawboard wastes were carried on with a view to developing a practicable filtration process which would relieve the paper mills of the necessity of maintaining settling ponds over large areas of land. An effluent was obtained in which it was demonstrated that fish could live. It possesses a sanitary quality such that samples were not putrescible when stored in stoppered bottles at room temperature for periods of about four days.

Recent official reports from England, states the *Vocational Summary*, give the number of men totally blinded in the war as 1,415. Belgium reported only 28, Canada 120, and the United States, according to statistics compiled by Major Henderson, Fort McHenry, only 75.

NOTES AND COMMENT

THE AMERICAN MEDICAL ASSOCIATION CONVENTION

THERE were many things of unusual interest at the Victory Meeting of the American Medical Association at Atlantic City. The celebration of national victory and the part which the medical profession played in it was the outstanding feature, but the discussions and forecast of new and important problems for the profession to help solve took an important place. The enrollment was the largest ever recorded for a convention of the Association held away from the centers where casual attendance is large, 4,929 physicians having been registered during the week.

The part which the medical profession played during the war was naturally uppermost in the victory celebration. The fact that 38,000 doctors, more than one-fourth of the active physicians of the country, were enlisted in the army and navy was enough to stir the enthusiasm of the assembled members of the profession. What those 38,000 physicians did in preventing disease, caring for the wounded, and restoring men was recounted by the president, Alexander Lambert, in his inaugural address, and by numerous speakers at general and sectional meetings.

The presence of representatives of the medical profession of allied countries added much to the notable occasion and served to emphasize the harmony of spirit and of effort which has crowned the success of the allies and which should now be largely promoted for the solution of the problems of peace. The war has brought about at least one definite result, namely, the recognition of the fact that medical and health problems are international and world-wide. The rapid extension of

public health activities in several foreign countries testifies of the strides made because of the demands created by the war.

In its general and business meetings the convention turned its attention actively to the new problems of preventive medicine, public health, industrial medicine and surgery, social insurance against sickness, the publication of special medical journals, narcotic drug addiction, influenza and pneumonia, venereal disease, rehabilitation of cripples of war and industry, and the application of the new knowledge of medicine and surgery in civil life. In all of these subjects there was an evident underlying purpose to broaden the influence of medicine by making its application more widespread and its effect more directly social.

One of the important suggestions which received definite action was that the American Medical Association should provide for the publication of a popular or semi-popular journal of health and medicine. This proposal which has been considered at previous meetings has now definitely gone to the executive committee for action. The intent of the publication was stated to be an endeavor to bring to the people a knowledge of what the medical profession is really trying to do.

There were numerous recommendations by speakers and committees for a national department of health and resolutions approving the expenditure of at least \$1,500,000 for a Federal survey of influenza were adopted.

The recognition of industrial medicine by giving to it the entire section of Miscellaneous Topics was a forward step in placing it as one of the new and important specialties of medicine. The

papers presented in this section formed one of the best contributions to the subject which has ever been made.

The meetings of allied organizations at Atlantic City during the same week and the following week added greatly to the convention interest. There were three solid weeks of human interest and constructive work beginning with the National and Jewish conferences of social work, continuing through the meeting of the American Medical Association, and ending with the conventions of special societies and the National Tuberculosis Association.

MORTALITY STATISTICS FOR 1917

THE annual inventory of mortality has again been made up. The Census Bureau's summary of statistics of deaths for 1917 has just been issued and it shows that during 1917 the registration area of the United States had a death rate of 14.2 per thousand of population. This rate is slightly higher than in 1916, rate being 14.2 for 1916. The corresponding rates for previous years were:

1915	13.5
1914	13.6
1913	14.1
1912	13.9
1911	14.2
1906-1910	15.5
1901-1905	15.9

Of the deaths recorded more than one-third were due to heart disease, pneumonia, and tuberculosis, and another third resulted from Bright's disease and nephritis, apoplexy, cancer, diarrhea, and enteritis, arterial diseases, influenza, diabetes, diphtheria, and bronchitis.

These figures should serve to emphasize where the vital effort of medical and public health men should be centered. Vital statistics make an excellent compass to guide preventive movements. If twelve diseases are causing two-thirds of the deaths in the United States, those twelve diseases ought to be studied with intensity by every public and private agency. The progress of medicine indicates that science can isolate eventually the causes of disease, and the concentration of attention of scientists, backed by ample support, can do much to reduce materially the deaths from the most destructive causes.

The Census Bureau reports that twenty-seven states and the District of Columbia, and forty-three cities in non-registration area states, with a total estimated population of 75,000,000, or about 73 per cent of the population of the United States, make up the registration area. The first step in the rounding up of the causes of death

should be the complete registration of all deaths in the country. That twenty-one states should have so little interest in this subject is a serious handicap.

SAFEGUARDING THE PHYSICIAN

TWO incidents have served lately to focus our attention upon the welfare of the physician. The first was the receipt of a letter from a busy physician, one of the right sort who feels his obligation to contribute all that lies in his power toward the care of the sick and the solution of the various problems of organization now confronting the profession, in which he protests against his ever increasing duties and the oft repeated urge to greater effort by saying: "What about the welfare of the physician? Is not his well-being at least as important as that of any other class?"

The other incident is the case of a young and progressive physician, one who has done earnest and painstaking work every step of the way in his career, one in love with his profession whose field has broadened and his business grown at a steady pace up to the present time. Now he finds himself at the turning of the way. A larger opportunity opens, but he hesitates because he sees no time for additional duties and no possibility that he will be able to shoulder additional responsibility. If he does not take the step forward, certainly he has set his own limit upon his career.

That the welfare of a physician is as important as that of any other class goes without question. It may be considered even more important than others to the degree that the physician does a special work no one else can undertake, a work that benefits more people than any other. As a class physicians carry far more than their equitable share of the burdens of society.

The work cries to be done now. It cannot wait until younger men are educated to fill the ranks of scientific men. The only alternative is to make every possible effort to make effectual the present squad, and to prolong their activity over a longer period than has been that of the average working years of physicians. Very definite help for the physician needs to be devised, but certainly not by lessening his sense of responsibility, and certainly not by establishing a dead-line beyond which he may not develop. When the larger opportunity comes, the physician must not be too occupied with details to recognize it; he must somehow make himself ready for it, and that without detriment to himself physically or mentally.

When a business enterprise outgrows its quar-

ters or the office force attempting to handle it, expansion immediately takes place; the man in trade builds up an organization that in a measure frees him from the details of its management, one that earns for him whether he is in the immediate vicinity or not and frees him for broader activities.

The medical profession has been a one-man business, resting upon the personality, the skill, the activities, the actual presence of one man. That kind of a business is limited by the strength and endurance of one man and crashes when he collapses. Only his joy in his work and his absolute coordination in the prosecution of it enables the physician to stand the strain of his routine. What the physician needs to learn of the business man is organization, how to realize on his ability and to conserve his strength.

At the earliest moment when his business justifies it, let the physician associate himself with another man to help carry the load, if not another physician, then a technician who can relieve him of routine, or a laboratory apprentice, or the sort of a secretary who will receive special training and become an invaluable aid in his day's work. Let him encourage such an assistant to do all he is capable of handling in the way of records, scientific and otherwise, reading and annotation. A physician who early puts this sort of a check on himself and his work

PRESIDENT-ELECT OF AMERICAN MEDICAL ASSOCIATION

REAR ADMIRAL WILLIAM C. BRAISTED, Surgeon General, United States Navy, president-elect of the American Medical Association. (Copyright by Harris & Ewing, photographers.)

THE American Medical Association at the Victory Meeting selected Rear Admiral William C. Braisted, Surgeon General of the United States Navy, as the president-elect of the Association, a fitting recognition of service and of the victory occasion. Dr. Braisted has had a long career of scientific public service. Born in 1865, he was graduated from Michigan University in 1883, and Columbia University Medical School in 1886, made assistant surgeon, United States Navy in 1890, became successively passed assistant surgeon, surgeon, medical inspector, fleet surgeon, United States medical representative in the Russo-Japanese war, and finally Surgeon General in 1914. His entire record has been one of substantial progress and fine public service. He has been twice honored by foreign governments, having received decorations from the Emperor of Japan and the President of Venezuela. President-elect Braisted will become the Acting President of the American Medical Association at the annual meeting in June, 1920, at New Orleans.

finds that his records become definite bases for statistics, his observations are not mere "impressions," he has more confidence in himself and his work. Confidence begets confidence, and he will find himself rated better by his fellows and by his clients. Moreover, he will not find himself so harassed by the details of his business; he will do more work, and better work. We have seen transformations like this take place in the records of physicians' offices. Details that had been dodged because they seemed difficult come up automatically and receive due attention and leave the physician pleased with himself because they are handled.

But it is not only in technical assistance that the physician finds help—the mechanical aids that note the forgotten point in the history, the lost address that throws him out of his schedule, the delayed appointments, the neglected account—so much as in the proper schedule for his reading. Every one demands that the physician be right up to the minute in his reading. As medical journals are published to-day they constitute a most formidable heterogeneous mass from which to sift and select his reading. It takes all a man's time and energy to cover the material in a single field. If he does not at the same time keep up on general matters he soon finds the scientific meetings a veritable tower of Babel where he cannot under-

stand even the language the others are speaking. For the busy physician library service is essential and it is available even for the men in remote districts by means of index cards and abstracts. A nominal sum annually will bring cards of all representative articles from which selection can be made. A slightly larger investment will bring abstracts of articles, verbatim translations of bits of necessary technic, an appraisal of articles, or complete bibliographies. It is "not so much to know the law as to know where to find it" and a man who introduces into his reading such a system as will insure that he keeps a survey of the literature will be abreast of the times. The grouped abstracts furnish him a basis for scheduled and constructive thinking instead of befuddled groping or spasmodic effort to keep up, and free him for original work. Moreover, two or more physicians in a community may pool their literature, and meet for exchange of thought. It is necessary that the physician do these things if he wishes to be ready for the larger opportunities as they arise, if he wants his work to be a live and growing thing, and if in the midst of his busy work he wants to find periods when he can permit himself absolute relaxation and rest.

THE PHYSICIAN'S INTEREST IN THE STANDARD OF LIVING

THE relationship between the standard of living and the health of the people is clear to every social observer. Physicians are keenly aware of the relationship because of daily observation of the economic problems of their patients who are often unable to provide some of the simple necessities for healthful living, and particularly the necessities for proper support during sickness and the means of restoration to health.

The article in this issue by Dr. Royal Meeker, entitled "Health and the American Standard of Living?" is commended for careful study as the latest authoritative summary of the existing standard of living as shown by a study of more than 13,000 family budgets in the leading cities of the country.

The essentials of healthful living are proper food, clothing, shelter, medical care, amusements, and insurance. These are all treated by Dr. Meeker with the aid of the statistical yardstick. From an analysis of the food schedules he estimated that at present it takes from fifty to sixty cents per day to supply enough food values for a man and that the normal American family consisting of husband, wife and three children under fifteen, living in the medium and large cities, must spend about \$610 a year for food.

This must indicate the necessity for an \$1,800 family income whereas the average family income is only a little over \$1,350. These figures indicate, he says, "That the workers of America are obliged to live on a diet too restricted and monotonous for the maintenance of as high a degree of efficiency and health as should be maintained as a reasonable minimum." If this be true of the average, what should we say of the millions who do not receive the average wage? Surely here is a problem for the physicians, dietitians, and sociologists to solve in order that people may provide more and make the most of what they are able to purchase.

The purchase of the other necessities of life with restricted means is only of slightly lesser importance. The family budget must be stretched to cover all and, when it is insufficient, or not scientifically spent, some essentials of health are bound to be left out.

One of the most neglected of the essentials of health is the failure to purchase adequate medical care.

Most of the diseases that arise out of malnutrition, bad housing conditions, monotony, and fatigue are slow of onset and are not likely to present the necessity for attention to-day, but to-morrow instead. The visit to the physician is postponed and neglect is added to the undermining process of lowered standards of living.

That the average family is unable to pay for adequate medical care is evidenced by the existence of so much sickness-subsidy of various types throughout the country and the many agencies designed to supply these indispensable services free or below cost. A remarkable increase is shown in these expenditures with the increase of income.

The budget figures show that medical expenses increase rapidly with income. The families having incomes of less than \$900 in Philadelphia and Boston spent \$24.15 and \$23.18, respectively, while those of \$2,500 income and above spent \$126.12 and \$67.42. "This indicates," says Dr. Meeker, "that those in the lower income groups are not able to pay for adequate medical and hospital service; for no one would contend that those in the higher income group are squandering money recklessly on physicians, surgeons, dentists, and the like."

The plain conclusion from the figures and from common observation is that the people of small incomes fail to take the ordinary precaution of calling a physician or visiting his office until a serious condition arises. The result is characterized as "a systemless system of medical sick benefits."

THE RISE OF SOCIAL MEDICINE

BY DR. RENÉ SAND, MEDICAL ADVISER TO THE BELGIAN MINISTRY OF LABOR; LECTURER ON INDUSTRIAL AND SOCIAL MEDICINE AT THE UNIVERSITY OF BRUSSELS

AMONG the factors which have won the war, organization and co-operation were the most prominent. If we stop to think of the improvements brought about during the last four years in our factories, in our armies, in the life of the people, we see that the scientific and the co-operative spirit have made the whole difference and have achieved wonders.

But as soon as we try to pervade our peace activities with these elements of success, we strike at two very paradoxical facts. The first is that the human-saving sciences have not kept pace with the other sciences. We only begin to know something about eugenics, about physiology of labor, about the factors affecting the growth of children—all things of first class importance for our prosperity and happiness. Other sciences, however, although they cannot boast the same usefulness, loom large in our museums and publications.

It seems that instead of doing the urgent job first, mankind has always preferred to begin with the less important task.

Where Medical Profession Lags

That is bad enough; but here comes the second point: it has been emphasized again and again that utilization of science has not kept pace with its advance. Lee¹ has once more pointed to this fact in a recent book, in which he tells what is known about the working of the human machine, and the little use that has been made of this knowledge. Plenty of other examples could be cited. We know perfectly well how to eradicate malaria and yellow fever, yet these diseases still claim many victims. We know that we could prevent half of the deaths which occur every year, and yet they are not prevented. Thirty per cent of the blind people would see if only a few drops of an antiseptic solution had been put in their eyes at the time they were born; and yet that

MEDICAL SCIENCE THE NUCLEUS OF COMMUNITY SERVICE

By enlarging the aims of medical science, by broadening its method, by dropping its academic and professional aloofness, the practice of medicine will tend to become more and more a nucleus of community service. The task demands frank recognition of the retarded progress in the human-saving sciences as the first step toward its correction.

The fruits of medical science are not for the esoteric few, but should be given the widest possible application, with the end in view of an enlightened public mind.

very simple precaution has not been taken. The reason for these deficiencies is that there is no program for the scientific organization of mankind, no agency to study such a program, no teaching given on the matter.

We will never reach the point where we really govern ourselves and master the world until the universities are made the centers of communities; until they become civilly constructive.

American universities are quickly moving in that direction. In the United States people have realized that a university is not primarily a place where young men play football and learn Greek or mathematics; neither is it in principle a school for lawyers or physicians, nor a museum where experts, in a comfortable environment, study at leisure some old Assyrian inscriptions. These academic activities are very valuable and necessary, but we must put foremost a higher and more general purpose—the welfare of the nation.

Newer Conceptions of Ideal

The constructive university will not include many more sciences than the university of to-day; it will rather teach them from another viewpoint. We explain to our undergraduates how to prevent tuberculosis by avoidance of contact, a well balanced diet, good housing conditions, and rest. Very well; but we do not tell them how to provide those things. The way public health should be taught would strike at the root of the question and proclaim with Surgeon General Gorgas that the greatest public health measure that can be introduced is a minimum wage law.

I would go a step farther than preventive medicine, and teach social medicine. There is a field between sociology, statistics, biology, medicine, hygiene, and philanthropy, which is a kind of no man's land. Some patrols start from the biology border, explore a little stretch, and then come back. The same occurs from the medicine border, and from every border. When two patrols com-

¹Lee, Frederic S.: *The Human Machine and Industrial Efficiency*. Longmans, Green & Co., 1918.

ing from different borders, meet each other, they sometimes fraternize; more often there is a big scientific fight. I do not mind very much this kind of fighting after having seen the other kind. The worst feature is that the patrols seldom meet, so that the knowledge which one border gains about the no man's land is lost for the others. There is no coordination of effort, no planning together, no team work.

What Is Social Medicine?

This could be avoided and a real need be met if we started frankly to organize that field under the auspices of social medicine.

Social medicine means the medical end of the social questions, or the social end of medical questions, as you prefer to put it.

Almost every medical question ends in a social question. Hygiene, for instance, was first thought of as an individual science and art, a kind of personal wisdom. You cannot, however, prevent disease by your own efforts, if your neighbor is not willing to do the same, if the whole community does not take up the matter. So individual hygiene was supplemented by public hygiene. That was only a further step towards the goal. It means a great progress to distribute pure water, to establish drainage and sewerage, to build isolation hospitals; but hygiene is not the mere art of keeping nuisances away; that is its negative part, if I may say so—no microbes, no flies, no bad smells, and so on. The positive part is much more important; it includes a comfortable home, good food, recreation, fresh air; and these things are intimately connected with economic and social conditions. So public medicine goes over to social medicine, an outcome of our time, and the basis of reconstruction work.

The same evolution occurred in medical practice. The relation between physician and patient was first purely individual; then the public element came in, and we provided hospitals, clinics, dispensaries, etc. But the necessity arose of supplementing medical diagnosis and medical treatment by social diagnosis and social treatment. American vision led the way; hospital social service was started; social workers and doctors began to cooperate.

Hospitals as Health Centers

I think we must go still further, and make of every physician a social worker, of every hospital, a community center. That this need is widely felt is shown by a recent decision of the London Hospital trustees; the consulting physicians and surgeons are to be replaced by full-time resident doctors, who will not only be in charge of the

hospital wards and out-patient departments, but will also extend their work to the neighborhood. In this way the hospital and the community will be brought into the closest possible contact, and the students will be fully prepared for their future activities. Hitherto they have practiced in the hospital only, where everything is provided, and no obstacle blocks the way to treatment. How different things are when the patient is visited in his house, and it is realized that therapeutics are often of little importance as compared to the relief of economic conditions, to readjustment of work and family life.

The rehabilitation of the crippled soldier points in the same direction; it has taught us that physical reconstruction cannot be separated from vocational reconstruction. And so our hospitals have been put into relation with industry and labor, a lesson which is now being taken into account for the rehabilitation of the industrial cripple. Once more considerable progress has been made by breaking down the fence which surrounded the hospital.

Life does not recognize our nicely drawn classifications. They are valuable in so far as they make learning, research, or administration easier. They become a nuisance as soon as they obscure in our minds the interdependence of the innumerable factors which affect mankind.

The Social Sciences Merge

Medical questions simply cannot be separated from social problems.

Study delinquency, and you learn that it is intimately connected with mental abnormalities.

Deal with the wage question, and you see that infantile mortality increases terribly as the family income decreases.

Investigate labor conditions, and you cannot avoid bringing physiology and pathology of fatigue into the field of research.

One enters into charitable work, only to find that disease, and especially tuberculosis, is one of the main factors of poverty.

Social medicine, which bridges the gap between sociology and medicine, would have been constituted long ago were it not for the fact that it needs to teach the physicians the biological, statistical, and social methods. Now, biological methods the actual or future physician will accept without too great trouble. There will be more resistance to statistical methods, as they need the use of higher mathematics, and fumbling about in terrible books like the Census; but even that, the better type of undergraduate or doctor will admit finally, on account of the scientific stamp that statistics receive from mathematics.

When it comes to sociological methods, however, the average medical man revolts; surveys, inquiries, social case work, all seem too human to be scientific, and they mix one up with all kinds of social questions, nearly related to political questions. That is a slippery field.

A Very Old Science

Yet we have got to plough up this field, and it will give us the richest crop that science has ever reaped, because then we will no more guess, we will *know*, about the social questions.

No progressive law, be it a child welfare law, a labor law, a housing law, a wages law, can be effective unless it is based on social medicine. No such law can be enforced until public opinion is enlightened about social medicine, which is after all a very old science. Hippocrates, Galen, Pliny the Younger, Paracelcus, Ramazzini have long since mentioned the workmen's diseases.

The name social medicine was coined in France about 1840, and was given prominence by Rudolf Virchow in 1848. After a period of silence it has begun to be revived in America, in Great Britain, in Germany. The American Public Health Association and the British Medical Association have had for some years Sections of Sociologic Medicine. There existed in Berlin an Association for Social Medicine and Medical Statistics. The Belgian Association for Social Medicine published a quarterly bulletin, and was making rapid progress when war broke out. Teaching in social medicine was given at the University of Brussels to doctors who wanted to secure the public health diploma.

Several American universities have started or are starting schools and hospitals of industrial medicine. Many of them are more or less closely connected with the schools of social work.

We can already foresee the time when every school of medicine will devote the greatest part of its activities to social medicine. By enlarging its aim and broadening its method, by dropping its academic and professional aloofness, Medicine will become the center of community service.

DR. HUBERT WORK ADVISES EARLY STANDARDIZING OF HOSPITALS

To hasten the standardization of hospitals and to bring within reach of the average family income the skill of the physician and surgeon in diagnosis and treatment, have become the chief concerns of the medical profession and the members of the American Medical Association, in the reconstruction that has begun since the doctor returned from war, according to Dr. Hubert Work, chairman of the War Committee of the American Medical Association, and Speaker of the House of Delegates of the Association at the Atlantic City meeting of last month.

The American College of Surgeons was commended in the address of the Speaker, and the cooperation of the two associations was strongly urged. Dr. Work called upon the House of Delegates of the American Medical Association to consider the advisability of recommending to the trustees that a Council on Hospital be created.

All detail relating to the hospital care of the sick would have the attention of a bureau of information and standardization. The bureau would seek the aid of experts in fixing standards in hospital architecture, construction, plumbing, organization, contagious diseases, general medicine, surgery, interns, practical nursing, and other factors.

The changed conditions which physicians face upon their return from military service challenge all the ability and foresight of the medical man, stated the speaker. Dr. Work said in part:

"Thoughtful men agree that we are entering on a new era in medicine which will compel the closest interrelation between physicians, hospitals, nursing, and the public. It is not probable that practice will again be followed as heretofore. The time is passing when the personality and skill of a single physician will satisfy his patrons, or command a fee measured only by the patient's ability to pay, for skill is no longer limited to a few."

"Teamwork of physicians and the evolution of the hospital, which provides all domestic and medical service, has given the public an economic idea which will hereafter direct the practice of medicine."

"Cities and large towns already have their hospitals; rural communities soon will have, state-aided no doubt, for it is a short step from state care of the insane to state care of all sick."

"The greatest future concern of the American Medical Association may be its direction and oversight of hospitals; the practicable achievements of its five councils, if you please, brought to bear on common centers for the cure of the sick."

The position of the practicing physician and the undergraduate in the medical school were subjects chosen for comment by the speaker, who said:

"It is evident that the relentless pressure of this association for higher college and professional standards, with their time and financial exactions on the one side and the decrease in disease through preventive medicine on the other, are grinding between them students and physicians of average opportunities."

"Medical requirements for practice demand at least seven years of schooling beyond the high school. In some universities, two degrees and nine years' time are demanded for graduation. That included in the average medical school curriculum costs so much in time and money that only the rich can attain it. The crossroads communities will soon have no qualified physician, and from necessity will revert to the opportunist and the mid-wife. Should undergraduate schools undertake to finish specialists in medicine—presumably the function of post-graduate schools?

"The primary function of a physician, to cure the sick, is submerged by the scientific ambition to diagnose rare diseases or a few ailments, with an inevitable loss of perspective necessary to the accomplished diagnostician. Failure to gain practical knowledge of the simple things in medicine tremendously depreciates recent graduates. American medical colleges are graduating medical scientists, and our hospitals, nursing specialists—both technicians and both out of reach of the family of average means."

The Kids' Friend

The late Colonel Theodore Roosevelt felt a personal interest in child welfare. He is here pictured inspecting a "Diet Squad"

Plenty of wholesome, well-cooked food put smiles on these faces and dimples in the kiddies' cheeks, and has made them healthier and stronger than many of their playmates.

The School Lunch Committee serves hot, noon-day lunches to Food Scouts.

The photograph above shows members of the Food Scouts at one of New York's schools being weighed before starting their diet test of a square meal extra each day.

The children are taught the right way to brush the teeth.

(Photo by International Film Service Co., Inc.)

His first hearty meal event for this boy. He likes its color, but eating fresh fruit is something new to him and he wants to see what it is before it goes into his mouth. The picture at the bottom of the page shows the girls of a New York children's home sunning themselves in steamer chairs a part of the daily routine at the home when the weather is pleasant.

The photograph above was taken at a booth in the Grand Central Palace Food Show, New York City, where five hundred pupils of Public School No. 50 were weighed and measured to demonstrate the beneficial effects of the health rules and the system laid out by child welfare organizations in conjunction with the United States Food Administration, for improving the health of the city's children.

The Food Scouts

A square meal extra each day for three months put brawn on these New York youngsters, who were not used to eating square meals.

WHAT IS THE AMERICAN STANDARD OF LIVING?

BY ROYAL MEEKER, B.Sc., PH.D., UNITED STATES COMMISSIONER OF LABOR STATISTICS, WASHINGTON, D. C.*

REFERENCE is constantly made in the press and in public utterances to the American standard of living, as if it were a standard as definite and well known as the foot, the pound, or the peck measure. Speakers and writers take it for granted that everybody knows what the much quoted American standard of living is although they do not specify what is included in it and, when asked for particulars they become vague and oratorical. It gets us no further toward an answer to be told that the American workingman is the best fed, best clothed, best housed, and most contented workman in the world. It may be accepted without argument that, occupation for occupation, the American workman receives higher money compensation than do European workers, and that his higher money wages actually enable him to purchase more of the necessities of life than are obtainable by the European workers for their wages.

More exact information is necessary to determine what the American standard of living means. The investigations into cost of living made prior to 1915 are of little help. The classic cost-of-living study made by the United States Bureau of Labor in 1901, and published in 1903 as the Eighteenth Annual Report of the Commissioner of Labor, helps but little toward the desired goal. Except in the case of food, all this study brings out is the cost of living—not the standard of living. Even for food this 1901 study does not afford exact enough information as to the quantities and kinds of food to enable one to determine whether the families studied were sufficiently nourished. The study made by Dr. Chapin is too limited in scope to reveal the American standard of living. It is also questionable if the families studied were truly representative American families.

The generalizations made in this paper are based on the results so far as they have been analyzed of the country-wide cost-of-living study

The fighting armies in France opened the eyes of industry to the economic benefits of medical science. Intelligent medical service, wise preventive measures, and the salvage of human lives by rehabilitation of the disabled, strengthened the allied armies to the point which brought victory to their arms.

How shall this new power for social good be kept at work in the era of peace, except if industry makes a fast principle of rehabilitation for the disabled?

There are many shortcomings in the mode of living that must be attended to if the world is to profit from the experiences of the war.

families studied were obtaining a sufficient number of calories and sufficient variety in their diets to maintain their members in health; (3) if possible to work out standards similar to the recognized dietary standards, for clothing, housing, fuel, house furnishings, education, amusement, medical care, insurance, and perhaps some other items which have been heretofore blanketed and lost under the term "miscellaneous"; (4) eventually to formulate tentative standard budgets to be used by wage adjustment boards in determining minimum and fair wage awards; (5) to enable the Bureau of Labor Statistics to compute a cost of living index number that will show variations in total family expenses in the same way as the retail food price index shows variations in the cost of the family food budget.

It is evident at once that such a study presents enormous difficulties. One should not, however, refrain from attempting an undertaking merely because it is difficult. Everything that is worth doing is difficult. The first great task was to find out what workingmen's families buy, how much they expend, and how much of each article bought they get for the money paid out. It is in many respects unfortunate that the study had to be made during 1918-19 when prices were abnormal, resulting in abnormalities in expenditure, and when such stress had to be laid upon the necessity of investing in Liberty Bonds. The distribution of expenditures over the items of the family budget were greatly disturbed by the rapid changes in prices and wages. The loan campaigns resulted in inducing workmen to curtail expenses

*Address delivered before the forty-sixth annual meeting of the National Conference of Social Work, Atlantic City, June 7, 1919.

for clothing, house furnishing, amusements, and perhaps even fuel, housing, and food itself, in order to invest in bonds. The result is unusually large savings reported and abnormally low expenditures for other items where curtailment is possible. Many families not only economized on clothes and house furnishings but actually skimped themselves on food, both because of the high prices and because of the intense Liberty Loan drives.

More than three hundred agents were employed by the Bureau of Labor Statistics to secure from housewives statements of their expenditure for an entire year. The information thus secured for the entire year by personal interview was checked in many instances by daily expense accounts, which many housewives were prevailed upon to keep over a period of not less than five weeks. These daily expense accounts are especially useful in checking up expenditures for food and other articles bought daily or weekly and easily forgotten.

Nearly 13,000 family schedules were obtained in seventy-one large cities and twenty-six small cities and towns in the different geographical sections of the country for incomes ranging from less than \$900 to more than \$2,500 per family. These family schedules are now being tabulated. It cannot be said yet whether all of the objects for which the cost of living study was undertaken will be attained or not. The actual expenses for the different items of consumption are now being tabulated by income-groups. Not only do we have the cost but in most instances we have the quantity of all important items of the family budget. The quantity bought is absolutely essential for working out standard budgets. Expenditures stated merely in sums of money are useless for the determination of the standard of living or of the quantitative change in the cost of this standard of living.

Food

Quantitative standards to measure the sufficiency of the family food budget have been worked out tentatively in dietary studies. Men do not eat, or wear, or burn dollars and cents. If the price of beef goes up we can eat less beef and more of some other protein rich food, and perhaps keep our money expense for food constant; but if the price of all food increases 100 per cent we cannot cut down our consumption of all food one-half so as to keep our food budget expense unchanged. To speak with scientific accuracy man does not live by loaves of bread, pounds of meat, pecks of potatoes, quarts of milk, etc. He lives by the energy stored in food which energy is measured in heat units called calories. Even this does not

tell the whole story of food because it makes a difference from what source the calories are derived. There must be a proper balance between proteins, fats, starches, sugars, cellulose, fruit acids, and mineral salts. The last three classes of foods furnish us no calories at all, but they are just as essential to a healthful diet as are the fats, sugars and starches which furnish a large quantity of calories. By far the best single measure of the sufficiency of a diet is, however, the calory. Unless the average active worker consumers and assimilates from 3,000 to 3,500 calories per day he will inevitably either lose weight, or efficiency as a worker, or both, and this regardless of the number of dollars he spends for food, or even the number of pounds of bread, beans, and beef he eats. Unfortunately, bread, beef, pork, and even eggs, and potatoes, vary considerably in the caloric content per pound. It would be a great step forward if while weights and measures are being reformed the law should be made to require that the prices of all foodstuffs must be expressed in terms of calories just as in Great Britain, and to some extent in this country, coal is sold, not by the ton, but by the British thermal unit. If it is possible to calculate the caloric content of the food for our furnaces, it is surely possible to do so for the food for our stomachs. It is, of course, highly desirable to eliminate from the diet of our steam boilers and engines as much slate, ash, and boulders as possible: it would seem even more desirable to eliminate from the diet of human beings the things that are sold as bread but are not bread, the bone that is sold for beef, and the gristle that is called pork chops by the butcher. There are no insuperable obstacles in the way of selling bread, beef, pork, eggs, milk, onions, corn, sugar, etc., by the 100 or 1,000 calories. It should be done and it can be done.

By the time people become educated to the point where they recognize that the important thing in regard to food is not its price per pound or quart, that oftentimes the cheapest food per pound is the most expensive per unit of nourishment, no doubt they will have learned also that man can not live by bread alone or even by calories alone. Fruits and vegetables must be used largely in a proper diet even though their caloric content is low. A proper balance between proteins, fats, starches, sugars, cellulose tissue, minerals, and acids is necessary for the maintenance of health.

Some considerable change in diet is shown since the 1901 study was made. This of course was to be expected in view of the greatly increased prices. The present study reveals, however, that the American family does not suffer from overfeeding as has been so frequently alleged. On

the contrary, in most of the communities studied the food purchased represents less than 3,500 calories per equivalent adult male. It is necessary to buy about 3,500 calories in order to secure 3,000 calories per adult male, which is considered to be the amount required by moderately active workers.

Granted that to maintain the average adult worker in health and efficiency, it requires approximately 3,000 calories of food energy consumed which amount can be obtained from about 3,500 calories of food energy purchased at the stores, how is this knowledge to be used to determine the adequacy of the food budget of a family consisting of husband, wife, and five children of 16, 13, 10, 5, and 2 years? In order to measure the food requirements of a family there must be established a consumption yardstick to measure the number of calories needed by each member of the family. Experiments have demonstrated that food consumption of adults varies approximately with the weight of the consumer. Women on the average are about 90 per cent as heavy as men, therefore, a woman is rated in food consumption as equal to 90 per cent of a man. Children of different ages are rated in food consumption as follows in terms of an adult man:

Ages above 14 years (males).....	100 per cent
11 to 14 years.....	90 per cent
7 to 10 years.....	75 per cent
4 to 6 years.....	40 per cent
3 years and under.....	15 per cent

These equivalents are quite rough but serve to express the food consumption of families of varying composition in terms of a common unit of measure, namely, the equivalent adult man.

The food requirements of the family above mentioned would be, according to this scale, equal to that of 5.1 adult men. Allowing 3,500 calories of food purchased per man, this family should use food analyzing not less than 17,850 calories each day of the year. These standards of measurement are but approximate, it is true, and deal with averages. There are very considerable individual deviations from the average. The average man does not exist, but the world is full of living, breathing men who look, act, and eat so much like the hypothetical average man that it requires an expert with microscope, measuring tape, and scales to tell the difference.

The family food budgets are now being analyzed, but it can be said with confidence that it requires to-day an expenditure of from 50 to 60 cents per man per day for food to secure a well balanced diet sufficient in the number of calories and in variety. This means that American families consisting of husband, wife, and three chil-

dren below the age of fifteen years, living in large and medium size cities, must spend about \$610 per annum for food to keep themselves properly nourished for health and efficiency. This expenditure for food goes with incomes of from \$1,800 to \$1,850, so we may say that American families on the average are not fully nourished until their yearly income reaches to \$1,800. These figures do not indicate that our people are to-day suffering from eating too much meat, or even too much of other foods not so expensive. The average income and the modal income both fall well below \$1,600. The modal income is about \$1,350 and the average not greatly higher. Conclusions must not be too hastily drawn from these figures. They do not mean that the working population is dying of slow starvation. Nothing of the sort; but they do indicate that the workers of America are obliged to live on a diet too restricted and monotonous for the maintenance of as high a degree of efficiency and health as should be maintained as a reasonable minimum. And it would seem that the most efficacious remedy is not higher wages, but rather improved systems for distributing and marketing foodstuffs, and education of housekeepers in the art of keeping house with emphasis on diets. Housekeeping is not exactly a lost art; it is one of the arts that has not yet been completely found.

Clothing

No standard has yet been devised for measuring the adequacy of expenditure for articles other than food. The adequacy of clothing, for instance, cannot be measured in pounds, calories, or square yards. It is interesting to note that actual expenditure for clothing in all income groups combined for wives and children of different ages conforms quite closely to the scale for food consumption. Unfortunately there is no unit of measure with which to determine whether the clothing bought is adequate or not. The charge so frequently made that the American working-man is extravagant in expenditures for clothing for himself and his family seems hardly borne out by the facts reported. Expenditures for clothing per adult male during the high-price year, 1918, ranged from a minimum of \$30 in the lowest income-group to about \$180 in the highest income-group. The average clothing expenditure for the modal income of \$1,350 is probably not more than \$90. This does not seem to give much room for extravagance in clothing at the existing prices. Probably this sum is sufficient to enable the prudent and economical housewife to keep her family clothed warmly enough, but it does not leave much margin for style. Clothes were first invented, not for protection against heat, cold, and

wet, but for adornment and it is for the purpose of ornamentation largely that clothes are worn to-day. The bizarre notions of beauty possessed by the designers of clothing are incomprehensible to ordinary mortals, but as long as society accepts these ridiculous and often health-impairing standards of dress, society must stand ready to provide the worker with a wage sufficient to enable him to conform to the accepted fashion. It is repugnant to our sense of right that the working classes should dress in a way to set them apart from the more well-to-do. Few men and women among the workers in this country are willing to appear in public unless they can dress near enough to the mode or the standard of fashion so as not to attract critical attention. It is very clear then that the clothing of the worker's family should not consist merely of material to protect them from the icy blasts of winter, the blazing rays of the sun, and the dews and deluges of heaven, but should possess something of that subtle something called style. Style is expensive. Also, there is no standard of style. There are not even standards of dress fabrics. However, standards need not be exact to know that \$90.00 per adult male per annum is not too much for clothes in the varied climate of the United States.

It is interesting to note that wives spend less for clothes than husbands until we reach the higher incomes, about \$1,800 per year. It is also of interest that when economies are necessary they are made largely at the expense of the wife's wardrobe. The first baby makes a cut in the mother's clothes money, and every addition to the family cuts deeper into this item. It is scarcely fair to say that American wives prefer clothes and upholstered parlor furniture to children. It costs money, pain, and sacrifice to bear and rear children, however, and the study of the Bureau of Labor Statistics shows with startling vividness the extent to which the mother is obliged to sacrifice her house and her personal adornment to her children.

Housing

According to the British housing experts, overcrowding does not begin until there are more than one person per room. If this standard be accepted as satisfactory then there is little overcrowding in American workingmen's families; however, while the average number of rooms per family is usually quite sufficient the average room is not so satisfactory. Unfortunately it was not feasible to make an intensive study of the size and suitability of the rooms occupied by the families studied. For the typical family of husband, wife, and three children under fifteen years,

there are in the cities for which tabulations are completed invariably more than one room per adult male. The rooms per person decline as the size of the family increases. Families having an income of \$1,300 also have well over one room per person. The number of rooms per person does not reveal whether housing is satisfactory. For example, the rooms per person is higher among colored families than among white families in Baltimore. No one would maintain, however, that housing conditions are better among the colored people than among the whites.

The amount spent for rent varied from \$105 per annum for the lowest income-group in Fall River, Mass., to \$355 per annum for the highest income-group in New York City. For the modal income of \$1,350 the average rent paid in large cities is probably not far from \$200 per annum for the typical family.

The study does not give a complete or typical picture of housing conditions among workers' families. In order to get comparable figures of family income and family expenditures for food, clothing, housing and other items, no families were scheduled who kept boarders and no families with more than two lodgers were taken. These rulings were absolutely necessary to confine the study to normal, natural families, but by so limiting the study no information was obtained as to the extent to which families resorted to taking boarders and the amount of overcrowding resulting from the almost universal practice of taking in lodgers during the housing shortage of the war period. It is a necessary function of the community to provide suitable houses for the people at reasonable rents. As long as the provision of houses is left to speculators and contractors the workers cannot be properly housed.

Fuel and Light

It is possible to determine from the information on the schedule whether the families studied used enough fuel to keep their houses comfortable, but the information has not yet been tabulated. It is reasonably certain, however, that the American family does consume abundant fuel so that the living room can be lived in during the winter. Artificial light is probably sufficient also.

House Furnishings

As for house furnishings all that the schedules give is the yearly expenditure. Nothing is known about the stock of household goods possessed by the average American working family. It should not be an impossible task for experts in domestic science to determine the minimum requirements in the way of standard house furnishings for the

typical family. A special intensive study could then be made to determine how near American families come to the minima.

Care of Health

Among the expenditures lumped as miscellaneous are some highly important and significant items. Expenditures for sickness and death are the most significant in this group. The amount and kind of medical, surgical, dental and other kinds of treatment in sickness required by the average American family can not be obtained from the family schedules. The amount paid out by each family on account of sickness is given on the schedules. And the average amounts can be computed for different income groups and for all groups combined. The average expenditures vary greatly from family to family and from group to group. In Philadelphia those having incomes less than \$900 spent on the average during the year \$24.15 for health care, while those with incomes of \$2,500 and more expended \$126.12. In Boston the expenditures for these two income groups were \$23.18 and \$67.42, respectively. The average for all incomes in all cities would probably be from \$45 to \$55.

Despite the great irregularities in the distribution of these expenditures for sickness there is a remarkable increase with the increase in amount of income. This indicates that those in the lower income groups are not able to pay for adequate medical and hospital service, for no one would contend that those in the higher income groups are squandering money recklessly on physicians, surgeons, dentists, and the like.

The value of these figures is greatly lessened by reason of the fact that so much wholly unregulated, uncontrolled, haphazard, unplanned, unintelligent, more or less voluntary, and wholly unrecognized sickness-subsidy prevails throughout the country. This means that the average worker is not able to pay full price for the medical, surgical, hospital, and dental services needed by himself and his family, so the community or subsidized hospitals give him these indispensable services free or below cost. The result is indifferent medical and hospital service at a cost impossible to estimate accurately because there is no uniformity of practice and no adequate public control. In Massachusetts it is estimated that the workmen's compensation cases sent to hospitals for treatment pay only about 50 per cent of the actual cost of the treatment. This is handing out sickness subsidies to employers and insurance companies, not to injured workmen. This is the worst form of protective subsidy to industry.

The workers who are driven by dire necessity to make use of the free wards in hospitals either

learn to hate and distrust all hospitals and medical men because they are not given proper treatment, or they become partially or wholly hospitalized because they survive the treatment meted out to them and rapidly learn to like the carbolated atmosphere of our hospital almshouses. This systemless system of medical sick benefits, bestowed not as the just and recognized due of the worker, but as charity handed out by a benevolent community or by private philanthropists, constitutes the worst possible form of sickness pensions that could possibly be devised. Voluntary benevolent sickness subsidies and pensions achieve the minimum of results at the maximum of cost. They reach but a minority of those who need medical and hospital care. These obvious defects of the existing system of sickness subsidies are not pointed out in order to condemn it and recommend its abolition. On the contrary, these subsidies are absolutely indispensable and cannot be abolished without very serious consequences unless something better is devised to replace them. It is useless to talk of paying the workers a wage sufficient to meet all needed sickness expenses. This would make the misfortunes of the sick redound to the profit of the well. The health of the workers never will be adequately cared for until a system of universal sickness or health insurance is substituted for the present system of sickness subsidies. No valid objection can be raised to the public paying a part of the expenses of such a system, as the public is in a large measure responsible for the unhealth which exists to-day. But the worker should pay a share, for he is responsible in some degree for sickness in his family. Above all he should feel when he receives medical, surgical, and hospital treatment, that he is receiving services which belong to him of right, and not alms, from either the state or private persons.

Selective Draft Lays Fallacy

The sickness and physical deficiencies revealed by the selective draft have happily laid forever the carefully fostered fallacy to the effect that the American workman is so well paid, so well nourished, housed, and clothed, and so intelligent, that he needs nothing in addition to the existing agencies to look after his exuberant good health. The quantitative consumption of health giving and health maintaining services in the average American family is certainly very much below what is necessary to attain and maintain reasonably good health. It is very clear that the medical profession and the hospitals must be more completely and effectively organized and directed for the purpose of improving the health of the community. Until this is done it is scarcely possible for the

average American family to buy the required amount of health service to keep health and efficiency up to a reasonable standard.

Insurance

Consideration of the adequacy of health expenses brings us directly to the subject of insurance against the hazards of death, sickness, accident, old-age and invalidity, and unemployment. In modern life, provision against these hazards is just as necessary as medical service, or, for that matter, food. The amounts spent by American families for life insurance in 1918 ranged from about \$10.00 in the lower income groups to about \$65.00 in the higher income groups. The average is probably not far from \$40. This amount paid each year in premiums for ordinary life and term life policies would give the average family sufficient protection against the hazard of death. Unfortunately the agents in the field found it impossible to distinguish between so-called industrial insurance and bona fide life insurance. It seems at first blush as if it should be easy to differentiate between them on the basis of cost alone, but the amount of the policies was frequently not obtainable from the housewife, so the cost per \$100 could not be ascertained. It was discovered, payments were very often accepted by the agents of the burial insurance companies semi-annually or even annually, so it was not possible to make the distinction on the basis of the terms of payment of the premium. About all it is possible to deduce from the schedules as to life insurance is that the workers pay enough on the average to secure sufficient protection against disastrous poverty resulting immediately from the death of the principal bread winner of the family. Whether they get this sufficient protection is another matter. As explained above it was impossible to get the quantity and kind of life insurance bought at the prevailing market prices. Furthermore, only a part of the workers are insured at all, and those who most need life insurance are least able to buy it.

While payments for life and burial insurance by the average American family are as large as can be afforded and should buy enough insurance adequately to protect the family, the case is entirely different as to casualty insurance and so-called "health insurance." The average expenditures for these two kinds of insurance ranged from nothing in the income-groups below \$900 to \$5.44 in the income-group \$1,800 to \$2,100 in Philadelphia. The amount of premiums paid by different families is very irregular. The average amounts paid by different income-groups and even by all income-groups in different cities obeys no statistical law. The average for all families in

Boston is 95 cents per annum, while for Philadelphia it is \$2.74. It is very evident that no appreciable insurance protection against the hazards of accidental injury or sickness is included in the budget of the American working-man's family. Yet these injuries occur many times more frequently than death, and their hazards are just as readily calculable as is the hazard of death. It is not possible for the worker to buy adequate protection against the hazards of injury from accident and sickness even at the exorbitant prices charged by the private companies because the companies do not sell the protection needed. The case is even worse with old age, invalidity, and unemployment. Some trade unions and a few establishments pay small benefits for old age and invalidity. Out-of-work benefits have been paid by a few trade unions in times of great stress. Unemployment is the one hazard that is purely industrial, and it causes more distress and social demoralization than any other hazard affecting the life and health of the workers. Yet nothing has been done about it by industry and next to nothing by society. The whole burden falls upon the individual worker except for the feeble, sporadic help given by a few trade unions. Industry should be made to pay the costs of production. A part of the costs of production under the present organization of industry is unemployment tempered by underemployment and overemployment. It would be a very simple matter to put the money costs of unemployment upon each industry in which employment is regularly irregular. This should be done. As it is now, the worker does not and cannot include in his budget protection against unemployment and the onset of old age and invalidity. Some unascertainable part of his trade union dues, if he pays any, goes for the purchase of an indefinitely inadequate amount of protection against these ills.

Insurance Stabilizes Family Life

The percentage spent for insurance in all forms is not large, but its importance is much greater than this percentage indicates. Insurance makes for stability of family life, by distributing throughout the community shocks that would crush individuals and families. The present cost of insurance is so high that the workers are debarred from purchasing enough of it. The protection offered by private profit seeking insurance companies is not secure and many inevitable contingencies are not included in their policies at all. Insurance is a relatively simple matter. It could be conducted as a community enterprise reaching all the people at half the expense now involved. The moral is obvious.

Amusements

Amusement is one of the most serious things in life. Wholesome laughter is as necessary to health and efficiency as good food and suitable raiment. Unlike the other wants considered, amusement is subjective, not objective and therefore no objective unit of measure is conceivable. It is wholly impossible to guess how much amusement is obtained from a 17-cent moving picture show. It is clear that large numbers of people must be amused by the movies else the picture houses would not be packed. It cannot be said, however, that the families which patronize the movies get any more fun out of life than those which stay at home or go to the church festival. You can't keep people from being amused. They will get fun out of the hardest conditions of life. Tom Sawyer, by using the most approved methods of the trust promoter and the professional advertiser elevated fence whitewashing from the lowest form of menial drudgery to the rank of the most popular outdoor sport in his home town, so that for the time swimming and fishing were forgotten. The variety and weirdness of the different forms of amusement are astonishing. Some people derive much genuine enjoyment from funerals; others seem to get quite as much fun out of grand opera. I once knew a physician of sound mind who got his recreation and amusement from directing a volunteer church choir. Truly in the realm of amusement "One man's meat is another man's poison." One man will listen to a lecture on the Russian drama and will be upbuildest and refreshed amazingly; his neighbor will be put to sleep, and another will be driven toward homicide by the same lecture. The number of movies, dances, concerts, and the like attended by a worker and his family has no recognizable relation to the quantity of amusement they have imbibed. While all admit that "All work and no play makes Jack a dull boy," it may well be doubted whether the play furnished by the movies will make Jack brighter or duller.

Expenditures for movies increase consistently with increasing income. Only 38 cents per annum was spent for movies by families having incomes under \$900 in Philadelphia, while the families having \$2,500 or over spent \$37.32 for movies. In Boston the range was from 87 cents to \$34.39. The average for all incomes was \$10.18 for Philadelphia, and \$6.49 for Boston. Other cities show much the same averages and range of expenditures. The total average expenditure for all amusements amounted to \$12.40 in Philadelphia and \$9.23 in Boston. We do not know whether this means that Philadelphia working people found existence more amusing than Boston work-

ers, or whether their lives being more sad they were driven to the movies and the pool parlors for cheer. We may assume that the sums spent for amusement in the income-groups above \$1,300 are sufficient for recreational and health needs.

Conclusion

From this very brief analysis of the data thus far worked up from the cost of living schedules it is very apparent that there is no such thing as the American standard of living in the sense of a very superior standard giving all the necessities, many of the comforts and a goodly supply of the luxuries of life. On the contrary it is found that there are as many different standards as there are different incomes and families of different sizes. In the lower income-groups the living conditions are hard indeed. The incomes of the lower-paid workers must be increased and the cost of food, clothing, and housing must be lowered to enable these families to meet the high costs of existence. Social legislation is needed to give them better and cheaper food, clothing, houses, medical treatment, and insurance. Even in the higher-income-groups conditions are not as easy as they are frequently pictured to us. Let us not be fooled by the cry that the American standard of living is the highest in the world. Let the minimum living standard in America be one that will support life in decency and health.

EXPANSION OF MEDICAL SERVICE

Though the American public is served by twice as many physicians in proportion to population as the most favored European country, an increasing demand for medical graduates and physicians in all branches of medical service has prompted the Council on Medical Education of the American Medical Association, in its annual report, to express the following convictions as to the needs of the medical profession, the public, and the medical colleges:

"There is an increasing demand for physicians for various lines of work," says the Council, "a demand which can be met only by continuing the high standards of preliminary and medical education now generally adopted, and by further improving our facilities for both undergraduate and graduate medical teaching. This demand for physicians is increasing for the following reasons:

"(a) The work in the public health and preventive medicine is being rapidly expanded especially along the lines of quarantine work, sanitary inspection, medical inspection of schools, etc.

"(b) There is an increasing demand for physicians who specialize in laboratory diagnostic work. Such positions now carry larger salaries and are attracting an increasing number of medical graduates.

"(c) There is an increasing demand also for full-time teachers in medical schools for both laboratory and clinical subjects. These places are not only paying better salaries than formerly, but are attractive to many on account of the opportunity for scientific experimentation and research.

"(d) The rapid development of insurance has brought

an increased demand for physicians who devote themselves entirely to such work. With the extension of industrial insurance this demand is bound to be still further increased.

"(e) The increased study and research being given to tuberculosis, to mental diseases, to cancer and other like problems, is attracting many who would otherwise continue in the practice of medicine.

"(f) The tremendous interest being aroused for the development of hospitals in smaller cities and rural communities will create a demand for recent graduates as resident physicians in such hospitals. Through the inability to secure interns, hospitals will be inclined to employ resident physicians for a series of years on progressively increased salaries.

"(g) In the reorganization and improvement of hospitals there is a growing demand for those to serve as superintendents who can combine their medical training with administrative ability."

MORTALITY STATISTICS FOR 1917

A death rate of 14.2 per 1,000 of population is officially announced as having occurred in the death-registration area of the continental area of the United States in 1917.

The Census Bureau released the mortality statistics of 1917 for publication during the last week of June. It is shown that 1,068,932 deaths occurred in the death-registration area, which comprises twenty-seven states, the District of Columbia, and forty-three cities in nonregistration states, with a total estimated population of 75,000,000, or about 73 per cent of the estimated population of the United States.

Of these deaths, nearly one-third were due to three causes—heart diseases, pneumonia, and tuberculosis. Almost another one-third resulted from the following nine causes: Bright's disease and nephritis, apoplexy, cancer, diarrhea and enteritis, arterial diseases, influenza, diabetes, diphtheria, and bronchitis.

The deaths from heart diseases (organic diseases of the heart and endocarditis) numbered 115,337, or 153.2 per 100,000 population. The death rate from this cause shows a noticeable decrease as compared with 1916, when it was 159.4 per 100,000. There have been fluctuations from year to year, but in general there has been a marked increase since 1900, the earliest year for which the annual mortality statistics were published, when the rate for heart diseases was only 123.1 per 100,000.

Pneumonia (including bronchopneumonia) was responsible for 112,821 deaths, or 149.8 per 100,000. This rate, although much lower than that for 1900 (180.5) or for several succeeding years, is higher than that for any year during the period 1908-1916. The lowest recorded rate for pneumonia was 127 per 100,000 in 1914. The mortality from this disease has fluctuated considerably from year to year since 1900, the general tendency having been downward until 1911 and upward from 1914 to 1917.

Tuberculosis in its various forms caused 110,285 deaths, of which 97,047 were due to tuberculosis of the lungs. The death rate from all forms of tuberculosis was 146.4 per 100,000, and from tuberculosis of the lungs, 128.9. The rate from tuberculosis of all forms declined continuously from 200.7 per 100,000 in 1904 to 141.6 per 100,000 in 1916, the decrease amounting to nearly 30 per cent; but for 1917 an increase is shown. Until 1912 more deaths were due to tuberculosis than to any other single cause, but in that year and during the period 1914-1917 the mortality from tuberculosis was less than that from heart diseases, and in 1917 it fell below that from pneumonia.

Deaths due to external causes of all kinds—accidental, suicidal, and homicidal—numbered 81,953 in 1917, corresponding to a rate of 108.8 per 100,000 population. The greatest number of deaths charged to any one accidental cause—11,114, or 14.8 per 100,000—is shown for falls. The rate for this cause varies but slightly from year to year. Next to falls, the greatest number of accidental deaths—8,649, or 11.5 per 100,000—resulted from railroad accidents and injuries.

The following table shows, for the death-registration area in continental United States in 1917, the total number of deaths and the death rate, by leading causes, together with the percentage which each cause contributed to the total:

TABLE WITH MORTALITY STATISTICS FOR 1917

CAUSE	NUMBER	RATE PER 100,000 POPULATION	PER CENT OF TOTAL
Organic diseases of the heart.....	115,337	153.2	10.8
Pneumonia (all forms).....	112,821	149.8	10.5
Tuberculosis (all forms).....	110,285	146.4	10.3
Tuberculosis of the lungs.....	97,047	128.9	9.1
Tubercular meningitis	6,092	8.1	0.6
Other forms of tuberculosis.....	7,146	9.5	0.7
External causes.....	81,953	108.8	7.7
Accidental falls	11,114	14.8	1.0
Suicide	10,056	13.4	0.9
Railroad accidents and injuries	8,649	11.5	0.8
Burns (excluding those due to conflagrations)	6,830	9.1	0.6
Automobile accidents and injuries	6,724	8.9	0.6
Homicide	5,781	7.7	0.5
Accidental drowning	5,550	7.4	0.5
Accidental absorption of deleterious gases, except in conflagrations	3,375	4.5	0.3
Mine accidents and injuries.....	2,623	3.5	0.2
Injuries by vehicles other than railroad cars, street cars, and automobiles	2,326	3.1	0.2
Streetcar accidents and injuries	2,277	3.0	0.2
Machinery accidents and injuries	2,112	2.8	0.2
Effects of heat (other than burns)	1,964	2.6	0.2
Other external causes.....	12,572	16.7	1.2
Acute nephritis and Bright's disease	80,912	107.4	7.6
Cerebral hemorrhage (apoplexy).....	62,431	82.9	5.9
Cancer	61,452	81.6	5.8
Diarrhea and enteritis.....	59,504	79.0	5.6
Congenital deformity and malformations	56,973	75.7	5.3
Arterial diseases—atheroma, aneurism, etc.	19,055	25.3	1.8
Influenza	12,974	17.2	1.2
Diabetes	12,750	16.9	1.2
Diphtheria	12,453	16.5	1.1
Bronchitis	12,311	16.3	1.1
Measles	10,745	14.3	1.0
Typhoid fever	10,113	13.4	0.9
Appendicitis and typhilitis	9,429	12.5	0.9
Respiratory diseases other than pneumonia and bronchitis	9,238	12.3	0.9
Hernia and intestinal obstructions	8,677	11.5	0.8
Cirrhosis of the liver.....	8,569	11.4	0.8
Whooping cough	7,837	10.4	0.7
Puerperal affections other than puerperal septicemia	7,317	9.7	0.7
Meningitis	6,890	9.1	0.6
Puerperal septicemia	5,211	6.9	0.5
Rheumatism	4,456	5.9	0.4
Scarlet fever	3,141	4.2	0.3
Erysipelas	2,866	3.8	0.3
Malaria	2,387	3.2	0.2
All other defined causes.....	147,235	195.5	13.8
Unknown or ill-defined causes.....	13,610	18.1	1.3
All causes	1,068,932	1,419.4	100.0

Keppel Now Red Cross Director Abroad

Dr. Frederick Paul Keppel, formerly Dean of Columbia College of Columbia University, assumed the office of Director of Foreign Operations with the American Red Cross on July 1st, and will represent the Executive Committee abroad in the Red Cross in foreign countries. Dr. Keppel resigns as Third Assistant Secretary of War to join the Red Cross. During the war he has been in charge of all matters relating to the social and physical well-being and morale of the men in the army.

MEDICINE AND INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

ECONOMIC PROGRESS OF MEDICINE

IT was, of course, just coincident, but nevertheless it seemed significant that the meeting of the American Medical Association overlapped the meetings of the American Academy of Medicine, the National Conference of Social Work and the American Federation of Labor. The juxtaposition of the discussions of medical science, social science, medico-social science, and labor problems served to emphasize to the forward-looking medical minds at Atlantic City how interdependent these subjects are. Even a hasty review of the programs indicates the close relationship. It is a happy sign of the times that many physicians attended some of these other conferences.

The presence of hundreds of the officers of the army medical corps, and officers of the navy, along with many distinguished officials in foreign uniforms, gave quite a military aspect to the Victory Meeting.

But, while this international aspect was evident on the Board Walk and in the meetings, it remained for some of the sectional meetings to disclose the fact that a new day has come for the science of medicine. Whereas the experiences arising from the war gave much zest to the papers presented and will continue to give new impetus to certain surgical and medical procedures, the outstanding fact remains that the medical mind has been definitely broadened and socialized by war problems. Physicians have come into close contact with the question of handling great groups of men; they have had to consider and handle masses of civilians not only abroad, but they have had to deal with those populations immediately surrounding our camps.

Perhaps 30 per cent of our active profession was thus forced to think in terms of the mass; to plan and carry out regulations designed to improve the health and morale of soldier and civilian—a gain in social thinking that is bound to leave its impress upon the public as well as the profession. This advantage should not be lost

sight of by those responsible for social progress. Fortunately, the day is past when medical publications can afford to neglect this broadened interest in public questions. It becomes rather their duty to foster this new spirit and thereby strengthen the influence of the profession in shaping the world's progress. Of this we may be sure, that the managing editors must either accept the challenge that the profession is not forward-looking in its programs and stimulate such leadership or resign all medico-social planning to the laity.

A hopeful instance of aggressive thinking was shown in the Section on Public Health and Preventive Medicine, a section which has shown remarkable growth in the past several years. Perhaps not the least reason for this progress has been the recent rather constant additions of subjects related to industrial hygiene.

It remained, however, for the papers presented under the topic of industrial medicine and surgery, this year assigned to the Miscellaneous Topics Section, to herald the modern spirit of medical thinking. The advancement toward social medicine in Belgium under war's stress was strikingly recited by Captain René Sand and will prove suggestive in the future for medical welfare. Mr. Little forcefully presented the economic pressure on business to help solve the health problems of the worker.

The discussion of the paper that pleaded for the introduction of courses for the teaching of public health and industrial medicine rightfully placed much of the responsibility for the economic progress of medicine and the upbuilding of national health upon the medical colleges.

The good attendance at the meetings, the active discussions, and the presence of many leaders of the profession gave assurance that the new specialty of industrial medicine has come to stay; that its practitioners are sensing their obligations not only to industry and the workers, but that they are determined that the profession at large shall play a more definite part in moulding public

opinion as regards legislative action, and which looks toward the improvement of public and personal health.

To judge from the discussions held big business is deeply interested and ready to pay for health extension work. It would be said indeed if the profession were found wanting in this regard and unprepared both by lack of trained men and medical organization to grasp the opportunities so presented of more widely preventing illness and suffering and more quickly and adequately rehabilitating the sick and injured. It is to be sin-

cerely hoped that the medical outposts so gained will be held, that the officers of the American Medical Association, as well as the officers of state and county medical societies, will give heed to the new note that has been struck; that the programs throughout this next year will continue the discussion of these subjects so fundamental to the future of the medical profession, and that out of the accumulated knowledge so gained some very definite recommendations be presented in formal papers before the entire profession at the next meeting of the Association.—EDITOR.

BRASS POISONING—SYMPTOMS AND DIAGNOSIS

BY R. P. ALBAUGH, M.D., FORMERLY DIRECTOR, DIVISION OF INDUSTRIAL HYGIENE, OHIO STATE DEPARTMENT OF HEALTH, COLUMBUS, OHIO*

BRASS is an alloy composed of copper and zinc. As these two metals combine in practically all proportions, many alloys are possible. Zinc being the cheaper of the two metals, its percentage is likely to be much increased until "cheap" yellow brass is formed. Brass poisoning is limited to those exposed to the inhalation of the whitish smoke and sublimation products from molten brass and zinc. Brass, in any condition of temperature short of that of the recent vaporous state of its components, produces no intoxication peculiar to itself. Toxic effects due to brass in the cold metallic state never occur. Authorities are rather generally agreed that zinc is responsible for brass chills, the syndrome having been produced in man by burning chemically pure zinc.

Symptoms.—Usually the symptoms appear several hours after exposure, and set in with a dry, parched throat, an irritating and unproductive cough, a feeling of constriction in the chest, lassitude, anorexia, often followed by nausea and vomiting. Within one to four hours chilly sensations are noticeable, while a dull headache develops. The chills rapidly increase into a distinct rigor, which may last from one-half to two or three hours. No amount of external heat seems to lessen the rigor. Muscular cramps and sharp joint pains usually accompany the chill. The symptoms end almost by crisis and are followed at once by a most profuse perspiration, while the prostration lasts for several hours longer. There may be fever or the temperature may be subnormal. The stage of perspiration is followed by a deep sleep from which the patient awakens with no apparent aftermath. However, a high rate of tuberculosis is observed among brass foundrymen. The dry,

parched respiratory membranes encourage alcoholism.

Diagnosis.—Formerly the affection was confused with malaria. Due to the closing of foundry windows in bad weather, the general breathing of fumes has induced so much illness as to cause a diagnosis of influenza to be made. Dust from alloys rich in copper often produce in workers, green-stained hair and a green tint to the perspiration, but these are without direct effects upon the health and should not be confused with brass poisoning, which is characterized by the malaria-like syndrome of chill.

Likewise, "brass itch," which is a rather common condition among brass polishers and which is due to the slight irritation of brass dust, combined with habits of uncleanness, should not be termed brass poisoning.

Prognosis.—Brass poisoning is characterized by the development of a form of temporary immunity, the absence of immediate serious or fatal consequences, and a lack of definite pathology. It is believed that the moulders consider the affection so commonplace that they do not usually go or send to the physician. For this reason physicians rarely have the opportunity of observing brass-founders' ague.

Treatment and Prevention.—There is no specific treatment for brass chills. Many observant workmen use mild emetics, claiming that the production of vomiting relieves the distressing symptoms at once. A good purge also seems beneficial. Many workmen seem to derive benefit from drinking hot milk to which pepper is added. Prevention depends on proper hygienic arrangements in foundries and smelters, regulation of the habits of workmen, and large, roomy quarters. All furnaces and furnace areas should be provided with hoods and exhausts to draw off escaping vapors.

*This article is the second of a series by Dr. Albaugh on the common industrial poisons.

NEW DEVELOPMENTS IN INDUSTRIAL MEDICINE AND ITS FUTURE

BY LIEUT. COL. HARRY E. MOCK, M.C., UNITED STATES ARMY*

WHEN the American Association of Industrial Physicians and Surgeons sprang into existence in 1916, at Detroit, it was recognized by its founders and its friends as a very husky youngster with high ideals and with a definite service to render to mankind. Even its most hopeful sponsors felt that several years must elapse before these ideals could possibly become an integral part of the national health program; but in four short years industrial medicine has emerged as one of the foremost specialties in our profession.

The newer conception of the supervision of the health of employees, the medical examination of applicants and of the old force, the prevention of disease and accidents by industrial hygiene and safety first, better medical and surgical treatment for the sick and injured, compensation and benefits, and the relation of this human maintenance work to other employee's service departments are developments of the last ten years. In 1916 only a few concerns had adopted this comprehensive system of health service, but since then hundreds of industries have installed a portion or all of the standards represented by the terms industrial medicine and surgery.

With the entrance of our Nation into the World War, and the year and a half of struggle necessary to meet the overwhelming emergency, great social and economic advances were made which otherwise would have required decades to accomplish. Industrial medicine, already established but little known outside its own ranks, was soon recognized as a force for preparedness. Its principles stood for industrial efficiency and maximum production, both so essential to a victorious ending of the war. Every industrial surgeon should feel justly proud of the part which his specialty played in maintaining the strength and efficiency of the great industrial army without whose support the military army would have been powerless.

A NATION OF LEADERS

Two things are necessary if this Nation, the model of a true Democracy for all the countries of the world, is to maintain its prestige, and its moral and economic leadership: it must conserve the health and energy of its 40,000,000 producers and providers; and it must add to the principle "all men are born equal," this further principle—"and must have the right to remain equal."

To conserve the Nation's man-power there must be a practical application of the scientific developments in medicine and all other branches of knowledge able to contribute to the conserving of human life.

industrial medicine the national recognition which it has finally attained.

The history of its part in the national preparedness program is a history of the new developments in industrial medicine, and to-day this association stands upon the threshhold of a great future, provided we continue to serve unselfishly the great masses, those who must produce and provide.

Prior to 1917 the outstanding milestones in industrial medicine were:

1. The installation of qualified medical staffs in several of the largest representative industries in the country.
2. The establishing of visiting nurses services.
3. The introduction of medical examinations of employees, naturally followed by thorough examination of applicants for work.
4. The creation of employee's service departments, also known as sociological or welfare departments, of which industrial medicine is a closely correlated service.
5. The organization of the National Safety Council with its health betterment section and the recognition of the industrial surgeon's part in accident prevention.
6. The organization of mutual benefit associations and, later, the enactment of employees' compensation laws in thirty-eight

The work of those who were forced to remain on the job in order to maintain the health of the working forces in the essential industries; of those who contributed to the education of the public by their writings and addresses; and of those who carried the principles of this service into the work of the Army, the Navy, the other Governmental health agencies, and into the Red Cross—all have been responsible in giving in-

*Address of the President of the American Association of Industrial Physicians and Surgeons delivered before the Fourth Annual Convention of that Association at Atlantic City, N. J., June, 1919. Authority to publish granted by the Surgeon General of the Army, June 6, 1919.

- states of the Union, in both of which advances industrial medicine had a very definite influence.
7. The enactment of laws, still very inadequate, for the discovery of, and in some cases the prevention of, occupational diseases.
 8. The creation of medical consultants for a few state departments of industry and labor. The most notable example is furnished by the states of Ohio, California, and Pennsylvania. The quarterly conferences of industrial surgeons in the latter state are famous, and have been responsible for great advances.
 9. The symposiums on industrial medicine in the American Medical Association, first held in 1915, and in many state medical associations, and, finally, the creation of a section on Industrial Hygiene in the American Public Health Association.
 10. The organization of the Conference Board of Physicians in Industrial Practice, and the contributions of this group to the general subject.
 11. The organization of the American Association of Industrial Physicians and Surgeons and the influence of this Association in elevating the standards of health service in industry.
 12. The establishment of occupational disease clinics in a few medical schools, and in at least two schools comprehensive courses on industrial medicine and surgery.
 13. Contributions of industrial surgeons to the study and prevention of tuberculosis, of cancer, of venereal diseases, of infections, and the study of health insurance and other great social and economic problems related to industry.

Medicine an Aid To War Production

In 1917 when this Nation sprang to arms the American Association of Industrial Physicians and Surgeons sent a resolution to the President setting forth the importance of supervising the health of the industrial army and offering the services of its members to the great cause. Letters and addresses from many sources were sent to various government agencies emphasizing the value of industrial medicine as a means of aiding in maximum production. As a result, in October, 1917, the Medical Section of the Council of National Defense called a conference of railway surgeons and industrial surgeons to discuss this problem. A committee known as the Industrial

Surgeons Committee of the Medical Section of the Council of National Defense was the direct outgrowth of this conference.

Federal Action

Already in the Labor Section of the Council of National Defense several committees dealing with various aspects of industrial hygiene had been appointed and had made extensive studies.

The reports of these committees, combined with the comprehensive program of the Industrial Surgeons Committee for maintaining the health of the working forces in industry, influenced several large concerns, and especially the mammoth governmental industries, to install many of the recommended standards.

Finally, in July, 1918, the President issued an executive order placing the various public health measures, except those of the Army and Navy, under the control of the United States Public Health Service. This bureau adopted the program of the Industrial Surgeons Committee, and extended its industrial hygiene section to incorporate this broader field.

The survey of the medical departments of hundreds of industries of the country by this section of the United States Public Health Service, the suggestions for improvement, the circulars of propaganda urging the installation of industrial medicine in essential industries, the efforts to have medical schools introduce courses on this subject, and the cooperation with the Department of Labor to better the relationship between employers and the employed represent one of the great advances in this specialty.

Before the war was over the United States Ship Building Corporation, the Ordnance Department of the Army, the Government arsenals and munition plants, the navy yards, the United States Employees Compensation Bureau, and the Railroad Administration had adopted many of the principles of industrial medicine. The War Department organized a medical staff, visiting nurses, and a welfare department for the thousands of civilian workers assembled in Washington. Later the United States Public Health Service took charge of many of these activities.

In the women's division of the Department of Labor a committee of Hazardous Occupations for Women was organized. Industrial physicians and surgeons were members of this committee although they were representing the United States Army and the United States Public Health Service. As a result of the work of this committee many standards for the prevention of disease and accidents to women workers were made, and several industries were influenced to adopt them.

In the army industrial medicine also played its role. The plans for the physical reconstruction and re-training of disabled soldiers were based largely upon the practical work along these lines which had already been done for disabled employees in certain industries. In addition to this our country profited by the experiences of other nations in reclaiming their disabled fighters. Hand in hand with our efforts to rehabilitate the disabled soldiers there has been maintained a nation-wide publicity campaign ever pointing to the need of reclaiming the civilian disabled. To-day it is safe to say that one of the newest developments in the field of industrial medicine is the awakened conscience on the part of our people to the great human wastage in industry, the need of preventing this prodigality, and the necessity of reclaiming those who become handicapped through disease or accidents. Already two states, New Jersey and Rhode Island, have enacted laws providing for proper therapeutic measures for the disabled from industry, re-training for remunerative occupations when necessary, and the proper employment of the handicapped. Six other states are considering similar laws and there is a rehabilitation bill now before Congress.

Again in the army the establishment of limited service and of Development Battalions was based chiefly upon one of the fundamental principles of industrial medicine, namely, the placement of men at occupations according to their physical qualifications. Until June, 1918, soldiers who were found by their physical examinations, at the time of reaching the camps, to have defects, or who developed defects during their training which unfitted them for full military service, were immediately discharged. A survey made in December, 1917, revealed the fact that there were tens of thousands of able-bodied soldiers, capable to go across and fight, who were on duty as clerks, typists, orderlies, fire guardsmen, and many other noncombative positions. Tens of thousands of the men who were being discharged because of defects unfitting them for full combat service were perfectly fit to be placed at these selected duties, while great numbers of the others could be developed or reclaimed for selected or even full military service. Finally this truth was driven home, and limited or selected service and development battalions for the reclamation of these defectives became one of the great man-power measures of the army. In six weeks twelve regiments of able-bodied soldiers were freed from non-combative service, replaced by limited service men, and went overseas to fight. In this work the medical officers and personnel officers, who correspond to employment managers, worked in close

unison. The men were picked for duty according to physical qualifications plus occupational qualifications. To-day these personnel officers are scattered throughout the industries of the country. They have learned one of the great lessons of industrial medicine and are missionaries carrying the need of the application of this principle to the great industrial army.

If the war had continued industrial medicine and the allied human engineering activities would have proved conclusively that these principles represent the greatest movement for conserving and developing the human resources yet inaugurated in the body politic. As it was, the war lasted sufficiently long to demonstrate the value of human maintenance in industry and to place it upon a national plane.

State Action

In several of the state governments during the last two years there has likewise been a tendency to pay greater attention to the health of the working people. One notable advancement in a few states has been the appointment of qualified surgeons as disinterested consultants to the state compensation board. This has resulted in a demand on the part of these commissions that employers furnish better medical and surgical care to employees. Insurance companies have been aroused to the false economy of employing cheap surgical attendance for injured workers. A fairer and more equitable settlement of claims has been noted. This has caused considerable scrutiny of the various state acts, and there is a growing feeling that many compensation acts are inadequate, that a standardization of employees' compensation laws is an urgent need if justice is to be rendered to the injured and to victims of occupational disease.

In a few states, notably Pennsylvania, Ohio, California, and Massachusetts, a closer relationship has been developed between the State Department of Health and the Department of Industry and Labor, resulting in the advancement of industrial medicine as a public health measure. This is causing a closer cooperation between the medical work in industries and the municipal public health departments. It is apparent that within a very short time industrial hygiene will be a definite function of public health.

Industrial health departments and two or three night clinics, made available for those who must work have demonstrated that many incipient diseases can be discovered early, while still curable, if facilities are afforded the working people to obtain proper diagnostic and medical care. As a result, pay clinics and centers for group diagnosis and treatment are beginning to spring up in in-

dustrial centers. Men trained in industrial medicine and surgery will find fruitful fields of endeavor in these pay clinics of the future. Instead of the working man being forced to consult, after working hours, some physician, unqualified by training or equipment properly to diagnose his case, these centers will permit him to secure at a reasonable cost for himself and his family the same advantages of special diagnosis and care now afforded only the rich, who pay excessive prices, or the poor, who receive free treatment.

Medical Schools

At least eight medical schools have embodied some branch of industrial medicine in their curricula. During the last year there has been a marked advancement on the part of at least two of these schools, and very comprehensive courses are now being prepared for the fall term. Laboratories are being installed for the scientific study of occupational diseases; methods of prevention of occupational diseases and accidents, and epidemiology in industry will be taught; special courses on industrial surgery and the medico-legal aspects of accident surgery will be presented by experienced industrial surgeons; the ramifications of an industrial health department and its relationship to other employees service departments will be included in these courses. Physicians and surgeons with long experience in the industrial field are being appointed to teach this new specialty. Several large industries have agreed to open their medical departments for practical demonstrations to small groups of students.

This newest development in industrial medicine and surgery bids fair to become the most momentous advance yet made. Instead of medical students being graduated with only the individualistic idea of the practice of medicine they will go forth with a vision of group medicine—the possibilities of prevention as applied to a large group—and the great economic and social aspects of our profession.

Publicity

Several publications have given considerable space to articles and abstracts dealing with various subjects related to this field. The reports of the conferences of Industrial Surgeons in Pennsylvania and the bulletins of our own association have served as excellent mediums for publicity; but within the last month another great advance has been made by the appearance of two journals devoted to this field of medicine. The *Journal of Industrial Hygiene* is exclusively a publication of articles dealing with industrial medicine and

surgery. Its scope is to be international, dealing with advances in this specialty in Europe as well as in America. MODERN MEDICINE is the name of the other journal. It covers the entire field of medico-sociology, and devotes a section of the magazine to industrial medicine. Both of these magazines will henceforth offer the best means of advancing the principles of our association.

Allied Associations

Six great national organizations have developed within the last eight years which deal with some phase of subject of the personnel in industry. These are the National Safety Council, the National Association of Industrial Engineers, the Western Efficiency Society, the Employment Managers Association, the National Association of Corporation Schools, and our own Association of Industrial Physicians and Surgeons. Other organizations deal with problems in which we are greatly interested, but community of interests should draw these six associations very closely together. Their principles aim chiefly at the problems of human maintenance in industry.

For years the National Safety Council has given great prominence to the subject of industrial medicine. The same is true of the National Association of Corporation Schools. It is noteworthy that the other three organizations have included papers by industrial physicians on their annual programs during the last two years.

This development has lead to the following suggestion: that because of the closely related interests of these organizations in the questions of human engineering, efficiency, proper placement, and the conservation of the health and working ability of employees, arrangements should be made whereby there can be established an interchange of ideas between these groups and a closer coordination in their efforts. Each succeeding program of these organizations should be a constructive one covering all phases of personnel work in industry and setting forth a line of endeavor for each special group during the ensuing year. Representatives of industry, labor, and the government should be invited as guests to attend the various meetings and participate in the discussions. Such coordinated effort would cause great progress in human engineering.

Red Cross

The future activities of the American Red Cross are now being discussed and the national and international programs of this most powerful organization are being prepared. It has been conclusively determined that this great war machine shall not disintegrate, that its service is not

limited to periods of calamity, but that in the future it must serve humanity by becoming a power in the field of prevention. Doctor Farrand, the new director of the American Red Cross, recognizes the wonderful opportunity for the prevention of disease and accidents furnished by the general adoption of the principles of industrial medicine. He is anxious to receive help and advice from this group so that the final program of the American Red Cross may include a wise policy in this direction. It is suggested, therefore, that this Association appoint a committee of three members, to be known as the Red Cross Committee of the American Association of Industrial Physicians and Surgeons. The function of this committee will be to discuss with the council of the American Red Cross the scope of its plans, and outline wherein the Red Cross can help in the field of industrial medicine, and wherein our Association can further their work.

The National Health Council

Three weeks ago there met in New York the presidents or representatives of sixteen national health associations. These various groups represented the fields of public health, tuberculosis, child welfare, child labor, visiting nursing, prevention of cancer, prevention of accidents, and industrial medicine and surgery. It was felt by all present that closer coordination must be developed between the great number of associations existing in this country and working in many cases for the same general results. To accomplish this it was decided that a national council consisting of a representative of each recognized national health association should be formed to work out a program of coordination between these groups. This movement marks one of the most forward steps in public health yet made in this country. In it may be seen the forerunner of a national health administration. It is indeed gratifying for our Association to be represented in such a council.

Education

It is necessary for the members of this Association to contribute both scientific and practical articles on the subject of industrial medicine to a greater extent than has been done in the past. While the growth of this specialty has been unusually rapid, yet its principles and standards are far from being universally adopted by all industries. There is still a preponderance of the old methods which beget human waste and human suffering. There are still many employers who, refusing to recognize the human appeal of this work, cannot see the dollar and cent returns of a comprehensive human maintenance service.

Therefore, as experience in this work develops, and its practicability is more and more demonstrated, members of this Association should write and publish the arguments which will serve to educate both industry and labor to the great value of applied industrial medicine. Many of the medical profession need this propaganda likewise.

The time has come when this Association should give careful consideration to this question of publicity. A publicity committee, therefore, is suggested.

Teaching

With the tendency of medical colleges to include courses on industrial medicine another future activity is offered to our Association. A committee should be appointed to stimulate the teaching of this subject in medical colleges, to scrutinize existing courses and endeavor to make them comprehensive, and to prepare an outline of the subjects which should be included under this term industrial medicine to be submitted to all medical colleges.

Legislation

At every session of Congress, and of the various state legislatures, bills are submitted which deal directly with problems related to industrial medicine. Some of these should have the strongest support, both as individuals and as an association, while others are pernicious and need opposition. In order to meet this situation, a legislative committee should be appointed.

Constructive Program

The fact that a few farsighted industrial concerns throughout the country have instituted programs for conserving the health of their employees, preventing accidents, bettering working and living conditions, providing a better wage, and even, in some cases, a participation in the profits of the business, bear striking testimony to the existence of faulty labor conditions. The re-establishment of human relationship in these concerns has resulted in loyalty and contentment among their working force, a recognition of the community of interest between the employers and the employees, and an increase in production. Some of the greatest capitalists of to-day testify that these betterment services for their employees pay big dividends.

The adoption of this policy by all industries will result in a conservation of the man-power of the Nation, an equalization of the privileges of democracy for all our people, and will tend to cure much of the increasing labor unrest directly due to selfishness on the part of and disagreement between capital and labor.

It is time for this Association to adopt a con-

structive program wherein its energies will be directed toward real service to mankind. The day is past when such an association as this can be content with an annual meeting devoted to the reading of papers. It is hoped, therefore, that the directors of this Association will be instructed to prepare immediately such a constructive program, and to arrange a plan whereby it can be inaugurated at once.

Conclusion

From the gloom and sacrifices of the recent world struggle our people have awakened to many conditions long existing in their midst, tolerated without effort at correction except when slowly accumulating public opinion has demanded certain changes.

As a result of this awakening it is realized as never before that the nations have been very negligent in conserving their man power, in utilizing their human forces most effectively, and in granting to all their people the equal right to live in peace and contentment and to share equitably in the fruits of their labor.

Greatest Asset of Nation Is Its Man Power

The United States to-day is recognized as the most powerful economic force in the world. Further, for all other countries it is the model of a true democracy. If it is to maintain these enviable positions two things are necessary: (1) It must conserve the health and energy of its 40,000,000 producers and providers; (2) it must add to the principle "all men are born equal" this further principle—and must have the right to remain equal.

To accomplish this end there must be a practical application of the scientific developments in medicine, education, industrial engineering, economics, and sociology, and all other branches able to contribute to the conserving of human life and to the development of human happiness.

No laws or governmental regulations will make possible these new conditions—the adoption of this new principle of equality—until the people desire and demand them. To await legislation to correct conditions belongs to the pre-war period.

To-day the community of interest between capital and labor, the spirit of fair play and justice which is manifested by many broad-visioned business men and many thoughtful labor leaders, and the thousands of our people who have become imbued with the ideal of unselfish service as the practical expression of their patriotism—all these furnish a force for the correction of present conditions more powerful than any legislative force could ever be.

The present moment marks a crisis in the history of our Nation. Either the old conditions exemplified by selfishness in every walk of life, both governmental and private, will continue to exist, thereby perpetuating labor unrest, anarchy, and war, or the new conditions, fostered by justice and service, will now replace the old, resulting in an equalization of the rights of men, and a real guarantee of future peace.

The future of this Association will be glorious, provided it measures up to the great opportunities unfolding in this reconstruction period.

Railway Surgeons Elect Chief

Dr. Clarence W. Hopkins, of Chicago, is the choice of the Association of American Railway Chief Surgeons for president of the organization. The following officers have been chosen for the ensuing year: Dr. Duncan Eve, Nashville, Tenn., vice president; Dr. Louis J. Mitchell, Chicago, secretary and treasurer.

REST PERIODS FOR INDUSTRIAL WORKERS

The necessity for rest periods in any prolonged or monotonous work has long been recognized. The objection to such periods on the grounds of loss of time and disorganization of discipline is made nil by the studies reported in Research Report No. 13 of the National Industrial Conference Board, January, 1919, which show that the aggregate of voluntary and irregular rest periods taken by employees is greater than periods designed for the special needs of the workers, while fatigue curves show such degree of renewed interest and activity after recuperation as actually increases the output. Man is not a machine and, when his mechanism slows down from fatigue he must be permitted rest and recreation, and oxygen to burn up his acid waste products if he is not finally to land in the human scrapheap of industry.

This report tabulates the findings in 388 establishments. The conclusions are based upon the reports of 104 concerns allowing regular rest periods. Of these only 82 gave definite information as to whether rest periods are granted only to selected workers and of these only 21 allowed rest periods to all employees. The consensus of opinion indicates that the output is not diminished by rest periods, but is often increased. Certain inaccuracies of work are eliminated. The workers feel better at the end of the day. Owing to collective psychophysical habits, conditioned by practice, the greatest amount is done the last part of the day, and employees so favored show less discontent than obtains among others.

There appears to be a tendency toward the organization of such rest periods looking toward specially designed corrective measures to induce relaxation and rest. Some light refreshment at such intervals is beneficial.

Fixed rest periods for workers at intervals within the work-hour are the exception in American establishments. Their desirability and their practical utility are largely determined by the particular type of work, the composition of the working force, the length of the working spell, and the special operating conditions in the individual establishment. No study has been made in this connection in relation to frequency of accidents and no relation has been noted to labor turnover. Managers are inclined to accept the rest period with growing appreciation.

HEALTH SUPERVISION FOR STOCKYARDS WORKERS AT ARMOUR AND COMPANY

AN industrial physician in charge of the medical organization and medical personnel of a large industry stands in the same relation to the employees in that industry as the public health officer at the head of a city or state health department toward the public. The employees are the public of the industrial physician. Their health,

comfort, and safety; their places of work and residence; the forms of employment and occupations in which they engage, are his concern. He is the health officer of their community.

The administrative duties of the physician or surgeon in industry closely parallel those of the municipal health officer, only being varied in the adapting of measures for health and sanitation to working groups instead of the general public. The contact which the industrial physician has with his public is even more direct than the municipal health officer's relationship with the individual citizens of his community.

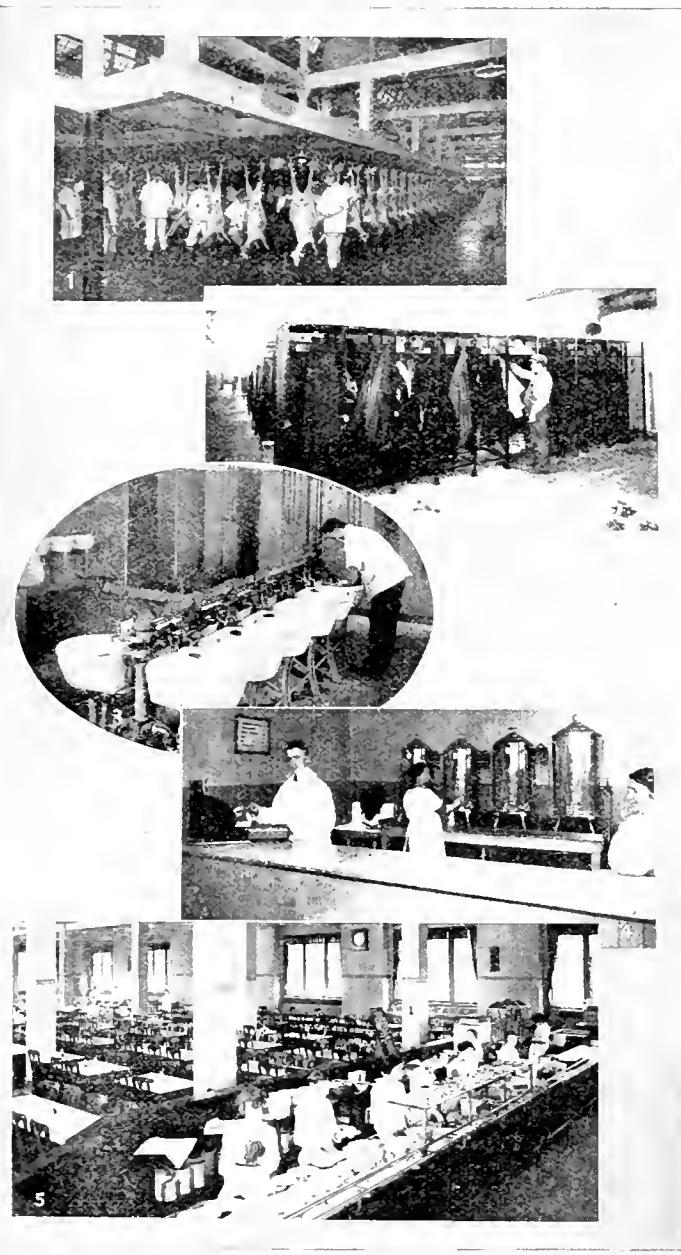

The working population in the Chicago stockyards is a typical American industrial community. Like a city divided into wards and precincts, the stockyards community has its subdivisions. One of these, with which the present study of health supervision will deal, is Armour and Company, the employers of 60,000 men and women in Chicago and elsewhere.

Getting a Job in Stockyards

When a new comer moves to a city, or to another neighborhood within his own city, he has no idea of consulting the city health officer, nor does that official think of the new resident and his family, or others of his kind, except in the mass. Herein is the point of divergence in the methods of public health departments and industrial health supervisors. And here is the difference in the practice and routine of industrial health supervision and public health administration. The advantage seems to lie on the side of the industrial physician.

The applicant for a position with Armour and Company must satisfy the examining physician in the medical office that he is physically sound and that his health and personal cleanliness are such as to warrant his being admitted to an organization which handles meat and foodstuffs for the tables of millions of people.

Like other large employers, Armour and Company has developed an employment management system which operates hand in hand with the medical department of the organization. The applicant answers the usual questions, fills out various blanks to

Quite in contrast with some of the ill-kept structures that sprung up in the stockyards district of Chicago during the early days of the packing houses, the modern buildings of Armour and Company and other large firms represent the best work of the architects who design the big food plants. The illustrations show (1) the well-ventilated, well-lighted sheep-killing plant of the Armour establishment; (2) a typical men's locker room; (3) a wash room; (4) a coffee booth and attendants in white aprons; and (5) the employee's cafeteria.

show his qualifications, and is given a classification. His assignment to work is not approved, however, until he has been given a careful physical examination to determine if he has any physical impairment which would be detrimental to him or to the company in the performance of the work in question.

For the examination of women applicants there is maintained a staff of experienced matrons and women physicians. Especial care is taken to assure the comfort and satisfaction of women and girls seeking employment in the Armour establishment, particularly if the ways of business are unfamiliar to the applicant.

It has been the aim of Armour and Company executives to avoid the tendency of department routine to become institutionalized in the methods and attitude of dealing with employees. Health supervision in the big packinghouse therefore has the double aim of utility and personal welfare.

Suitable arrangements in the design and construction of the modern structures which house the Armour plant and offices make it easy for workmen to acquire orderly habits about their work and about their persons. The departments in which the animals arrive, where they are prepared for the killing-room, and the buildings in which the slaughter is done, are scientifically ventilated, drained, and lighted. Adjacent to the work rooms are locker rooms, wash rooms, toilets, and shower baths, where employees can bathe, wash, and change their clothing.

The Homeward Bound Workman

The workman on his way home from the Armour plant is not garbed in dirty overalls, his brow is not marked with dirt and perspiration, and he does not look tired. He is washed clean, his clothes are neat, and he reaches home refreshed and alert.

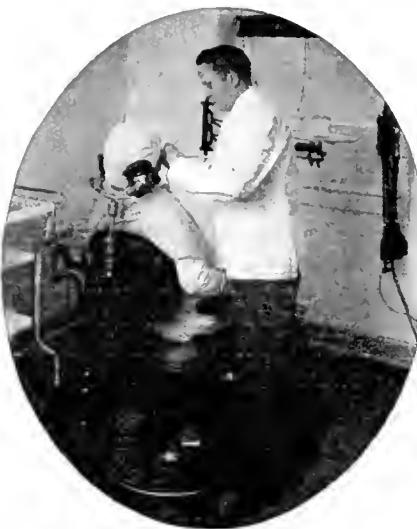

Scattered through the various buildings and floors are lunch rooms where wholesome food is served at small cost. The lunch rooms do not close up during the morning or afternoon, as in some industrial plants. Instead, women and girls, and sometimes the men, are urged to visit the lunchroom to get a cup of coffee or a sandwich when complaints are made of headache to nurses

from the medical or welfare department. A sandwich is often better than a headache powder.

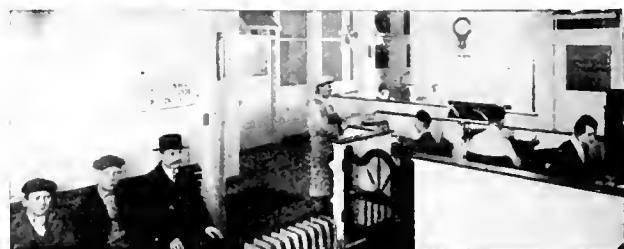

The nurses visit all departments at stated intervals, and are always on the lookout for the minor complaints and ailments which warn of something wrong. Nurses furnish tickets for the purchase of food, coffee, or bouillon, if they think such a treatment advisable.

These visiting nurses work under the direction of the Visiting Nurse Association of Chicago. Four nurses devote their entire time to visiting the women employees in the plant and to calling upon them at their homes. The same nurses assist in the general health supervision of the Armour community by giving noon-day talks. In the lunch rooms, rest rooms, or dressing rooms, groups assemble to hear these talks. The subjects vary with the interests of the listeners.

The medical provision for employees includes a large, fully-equipped, centrally-located hospital, with first aid and emergency rooms. Every Armour plant outside of Chicago is equipped with

Dental dispensary in the Welfare Department of the Chicago plant.

Waiting room at Armour hospital.

an emergency hospital also. The Chicago hospital employs six full-time physicians and a consulting surgeon.

Two examination rooms—one for women and one for men—and separate waiting rooms for men and women, are provided. Medical advice

An operating room in the emergency hospital for stockyards workers at the Armour plant.

and treatment are furnished without cost to the employee in all cases, including full treatment of whatever kind the illness requires.

Examinations are made under the direct supervision of the pathologist. The standard appliances and equipment of the modern hospital are available. In conjunction with the care and treatment of cases, instruction is given in matters of health and personal hygiene.

A dental infirmary is one of the indispensable features of the Armour program for health conservation. As part of the physical examination which an applicant for a position undergoes at the time of entering the organization, his teeth are examined and advice given as to the correc-

tion of any defect that may exist. The report of the dental department for the first six months of work shows that 840 men and women employees received dental treatment. Twenty-four nationalities were represented by those who availed themselves of the dental service.

The dentist does not attempt operative work, but seeks to impress upon employees the reasons why sound teeth and good health are closely related. He may in some cases recommend that a patient be sent to a practising dentist outside for treatment at the expense of the company, if an employee is not financially able to bear the cost himself.

Health of Office Workers

The problem of health for those engaged in work of a sedentary nature has been separately studied and a system of corrective health supervision for desk workers is the result. Yearly physical examinations are made of all office workers. A gymnasium is provided for their use. If the examination reveals a physical defect which can be overcome by proper habits, exercise, or special treatment, the employee is guided in the way best suited to overcome the trouble. Facilities are at hand for thermal, electric, heat, and massage treatments for those having need of them.

In the same way special attention is given to the comfort and health of women office workers. The welfare department maintains a rest room and works in cooperation with the visiting nurses.

Closely related to the system of health supervision are the numerous activities in athletics, and the social features of community life in the Armour stockyards organization. Educational facilities as well are combined with the other specialties of employees' service.

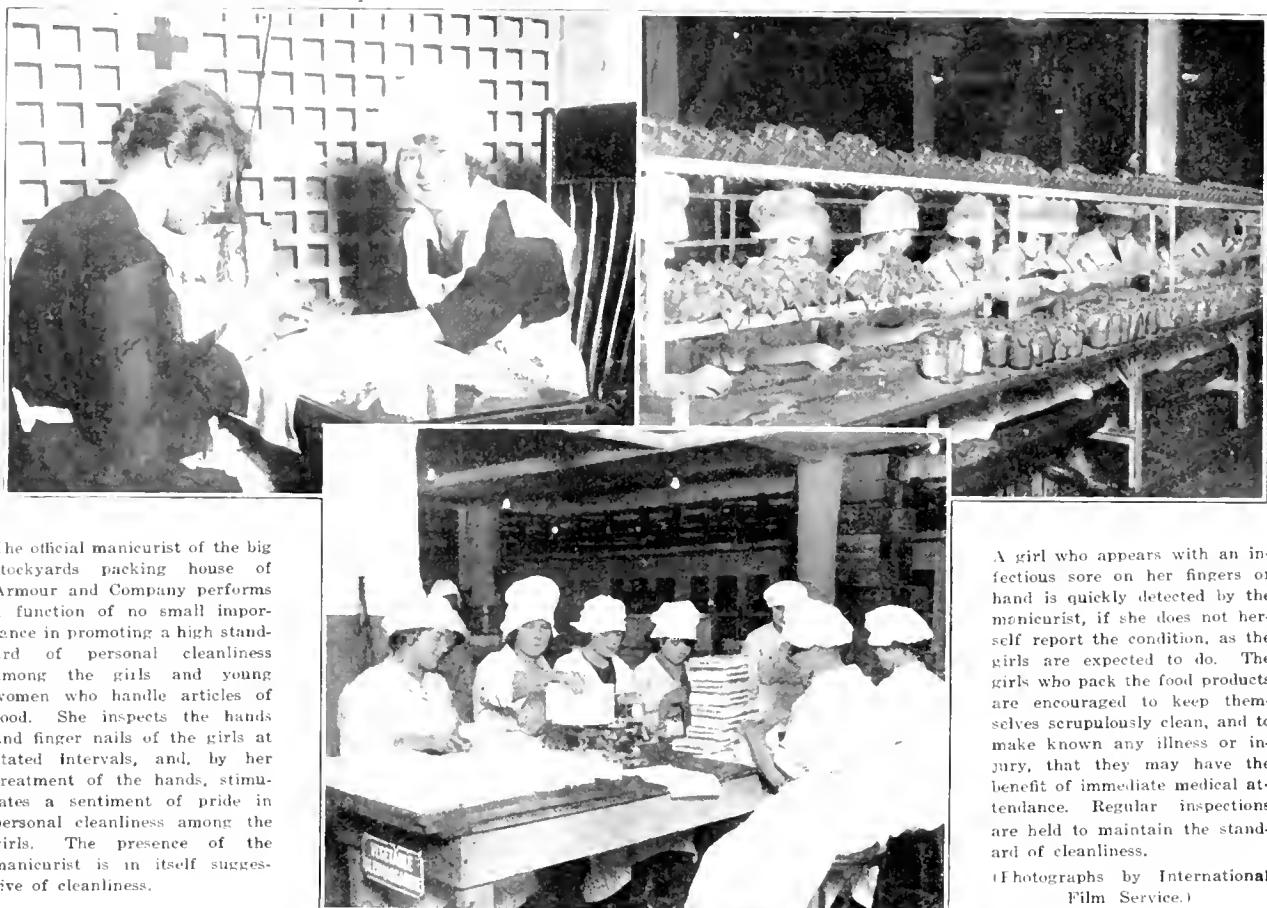

One of the most practical and interesting phases of educational work consists of the English class for foreign born workmen. This was opened several weeks ago in the employment office, by the company, in co-operation with the Chicago Board of Education.

The study of English is closely related to the safety and health of the workers. Many of the lessons relate to such subjects as the eyes, feet and other important members and urge the workers to take such precautions as are necessary in a large industrial establishment.

The classes have an enrollment of 400 students who spend an hour each several times

The gymnasium of Armour and Company for stockyards workers and a few of the facilities it provides: (1) Office employees go a-swimming. (2) A gymnasium class. (3) The Armour Gymnasium. (4) Examination by expert in drugless methods of treatment. (5) Physiotherapy for employees.

The official manicurist of the big stockyards packing house of Armour and Company performs a function of no small importance in promoting a high standard of personal cleanliness among the girls and young women who handle articles of food. She inspects the hands and finger nails of the girls at stated intervals, and, by her treatment of the hands, stimulates a sentiment of pride in personal cleanliness among the girls. The presence of the manicurist is in itself suggestive of cleanliness.

A girl who appears with an infectious sore on her fingers or hand is quickly detected by the manicurist, if she does not herself report the condition, as the girls are expected to do. The girls who pack the food products are encouraged to keep themselves scrupulously clean, and to make known any illness or injury, that they may have the benefit of immediate medical attendance. Regular inspections are held to maintain the standard of cleanliness.

(Photographs by International Film Service.)

a week under the instruction of an earnest teacher who understands seven different languages but confines his teaching strictly to English. There are fifty-two different nationalities represented at the Chicago plant and while they are not all included in the English class a large number are, Poles predominating.

Taken all together, the Armour community and public might be viewed as the cross section of any modern, American industry. Not least in the picture is the public health officer of the Armour plant—the physician of industry and his staff of assistants and nurses. Their function in supervising the health of employees and the sanitation of working places bears the same relationship to employment management as that of the commercial or industrial engineer in industrial management.

EDUCATIONAL NEEDS OF THE MEDICAL PROFESSION

"One lesson of the war which stands out with great distinctness is the necessity for the American Medical Association to continue its unceasing struggle to raise the standards of medical education in this country. Such are the increasing demands made on the medical profession that the

young men entering it today must realize that the broad and excellent education obtainable is none too good. It is not asking too much to require that all medical schools which are permitted to continue should soon be raised to the A Class.

There is another urgent educational need in this country that should be taken up immediately: that is, increase in the postgraduate opportunities for medical study. The opportunities that are presented in this country are practically undeveloped. It is for the profession to develop them, and every member of the Medical Corps of the army should be given an opportunity to avail himself, for a certain number of weeks each year, of the chance to study some branch of medicine or surgery at some medical center—not required to do it at his own expense, but detailed by the government to take up, for a definite number of weeks, his chosen branch of study. Physicians acquire their knowledge best by daily contact with opportunities which broaden their experiences. The opportunity to do this at short intervals, rather than at intervals of two, three or five years, would produce better results."—Alexander Lambert, presidential address, seventeenth annual session, American Medical Association, Atlantic City, N. J., June, 1919.

EMPLOYMENT MANAGEMENT AND INDUSTRIAL MEDICINE

BY OTTO P. GEIER, M.D., DIRECTOR EMPLOYEES' SERVICE DEPARTMENT, CINCINNATI MILLING MACHINE COMPANY, CINCINNATI, OHIO*

WHEN the great ledger account of the world war is closed; when the dead of all nations have been totalled; when their widows and orphaned children have been cared for; when the injured, the maimed, the blind, the helpless have been given a proper place in community life; when the proper recognition has been given those millions who dared to risk their lives that humanity's rights might be preserved; when the shackling burdens of destructive warfare have been distributed to the best ability of finite minds; when peace again shall reign, and free interchange of commerce begin to play,—the great outstanding fact from this world inventory will be that the appreciable valuation placed on human life has increased.

By curious anomaly that which has been held so cheap in war becomes so dear in the peace that follows. Then great masses of men were literally thrown out as targets for machine guns and cannon; now with infinite patience we are struggling to rehabilitate the wounded man so that he may again find an independent place for himself in industry and society. The great tidal emotions engendered by the war have swept us loose from all traditional anchorage; the chains of narrow, selfish, class feeling have been broken; our ships of state are afloat on the rough, uncharted social seas. Is wise pilotage at hand, or must we helplessly drift?

Life No Longer Cheap

These are mighty questions. Their answer in a democracy cannot be passed on to the other fellow—democracy makes this a personal and individual matter.

This very Association at this moment, unconscious though it may be of this fact, has a tremendous responsibility in finding the proper solution to problems which will go far toward marking that day when real justice to all men will abound.

BENEFITS FOURFOLD FROM AN INDUSTRIAL HEALTH CAMPAIGN

If employment managers wish to play a part in the most significant of world movements, they must have real understanding of the trend of industrial medicine.

The shameless waste and losses in industry caused from unnecessary illness, injuries, death, and invalidity are the issues that should lead to a great "health first" campaign, that in its infancy promises fourfold the results obtained from the "safety first" movement. The industrial health campaign is positive, productive, constructive.

For until the more fortunate, the rich and the near rich, shall approach and better understand the less fortunate, the poor and near poor, there is great danger ahead for all. Unless the strong, the intelligent, the tolerant, the sane, the sober-minded, whether rich or poor, bestir themselves so that social and economic justice may prevail, we may be sure that the unwise, the intolerant, the emotional, will produce a chaos in their ef-

forts to remove injustice. If the first group decline to bother themselves, they may now see at least how the second group solved the subject in Russia. If we are to find prompt answer to these vexing questions, we will have to stop folding our hands and sitting about waiting for statecraft to solve them. We must realize that these problems are personal and individual. If each employer will do unto his employees as he would like to be done with, the I. W. W. and the Bolshevik will vanish from our land.

Must Regain the Personal Touch

While it is advisable to think in terms of the mass, it is even more important to act in terms of the individual. The great industrial development of the last quarter century has made that increasingly difficult, but until industry intelligently, frankly, wisely faces that difficulty of mass estrangement and regains the personal touch and relationship, little progress will be made in these present social maladjustments.

Now what application have these principles just enunciated, to the employment manager and the industrial physician, whose joint responsibilities toward industrial relations we are to consider? Do these principles not suggest, at the outset, that the industrial relations department has a responsibility way beyond the confines of the particular industry which it serves? Do they not suggest that the net results possible of attainment from the combined efforts of numerous such industrial relations departments might weigh

*A paper read at Cleveland, Ohio, before the annual convention of the National Association of Employment Managers.

heavily in determining a better understanding between labor and capital, employer and employed, and thus hasten the day and contribute mightily to the solution of these most difficult social and economic problems? War has emphasized in no uncertain way the value of employment management. To many it first disclosed the value of the industrial physician in increased production through medical supervision. Whether the relatively new specialty, industrial medicine, and employment management will justify themselves in peace times will depend not primarily upon how these two affect production, but in the last analysis upon how nearly these two representatives of industrial relations have caught the spirit of the new day in industry. He indeed is unfortunate and narrow who still believes he serves the employer who does not first serve the employee.

Even more stupid is he who believes he can advance his own interests with the employer before he has laboriously and studiously advanced the interests of the employed. Of the three, he is the only one that can be fooled on this issue by himself. When industrial physicians and employment managers reach this high concept of their obligations toward men and society, they will begin to be of real service in this, their chosen work. Then they will put aside all petty, inter-departmental jealousies and through combined effort more nearly accomplish the task set before them—that of actual service to the employed. If we do this conscientiously we need not worry about the personal result on ourselves or on our employers.

Democratization of Industry

Thus far I have strayed very little from the text given me, "The Human Relations Department from the Standpoint of an Industrial Physician." I would that I might, in passing, say something that would hurry the day when the names "Welfare Department," "Industrial Relations," and others, would pass and the term "Employees' Service Department" be more generally adopted. The poet who said, "What's in a name?" lived before the day when welfare came into disrepute as "hell-fare." I, personally, prefer the term "Employees' Service Department" because of the infinite growth in function that its very name permits. It may originally mean only the service the employer wishes to furnish the employed; it may later also cover all such service that the employees may render to each other; but lastly and finally it may include all possible mutual service that these two may be to each other and the community. The term is demo-

cratic above all, and will hasten the day of the safe democratization of industry.

Let me say a word for the industrial physician of his place in industry and society. I assume that it is unnecessary for me to argue with this audience as to the value of a highly skilled, socially-minded physician in industry; of the unlimited number of natural contacts that he makes between the employer and employee; of the dignified place that he should hold in the councils of the company; of the infinite service that he may be to the men. I need not remind you that the cursory physical examination to control entrance is the meanest work he does for the company, but that the painstaking physical examination that he makes at the man's request, for diagnosis of illness, is a real contribution to society.

Careful surgical care of the injured may loom large in the eyes of the officials, but the constant education in matters of medical and surgical care has in it the making of men. Personal attention to minor injuries by the physician, instead of by a nurse or orderly, may seem expensive to the management, but if the confidence, begotten by such treatment leads to inquiries, at the same visit, about pains and aches or mental distress that, undiagnosed, will eventuate in invalidity and dependency, the original service is no longer trivial.

Laggards Retard Medical Advance

The most pathetic sight to me today is that company which, having established an employment department, safety work, and a first aid department with nurses, etc., fools itself into claiming it has a medical department when, as a matter of fact, it employs a physician or surgeon on part time, or perhaps one physician on full time to care for its several thousand or more employees. Such a company has never permitted a full-blooded, sympathetic physician to function, for the knowledge would soon have been forced upon it that right here lies the essence of real service to its employees. The men will of course not bring their confidences and their physical ailments to a cheap doctor, one who is inaccessible, or one whose whole heart is not in the work of the plant. And yet how quickly they avail themselves of intelligent, conscientious service for diagnosis, relief, and education, when such is accessible.

The industrial physician should undertake to treat any condition where his service measures up to that obtainable by the worker on the outside, but he may be equally sure that his initial diagnosis and reference of the patient to qualified physicians and expert consultants, proper hospitals, etc., on the outside, are perhaps an equal con-

tribution to the men as a whole. To keep these unfortunate men out of the hands of advertising dentists and quack doctors is a service not to be measured.

High type of medical supervision of employees is costly, as is high type of plant management. One deals with design, raw products, replaceable machinery, output and sales; the other with human beings, exposed to the wear and tear of production, occupational disease, and ailments which, if undiagnosed, may consign the sufferers to the human scrap heap of society. The work of the plant physician is today the concern of every forward-looking plant executive. This type of plant manager is a better executive through the knowledge gained of his force through the proper industrial physician, and to that extent he lowers the unit cost of production.

III Health a Burden on Industry

America will have to husband her human resources if she would meet the competition of nations after this war. Industry has a real duty in this direction, not only for the men temporarily employed by her, but for those in society at large. Industry should be first to lead in health crusades, should especially support legislation and other measures looking to the increase of facilities for preventive medicine. Industry can especially afford financial support and favor for the teaching of industrial medicine, as well as for the increased application of diagnostic group medicine. For it is the failure to secure the results of good health, productivity, and happiness that is a considerable drag on industry to-day. We may distribute the burden of this waste in health values through compulsory sickness insurance, for instance, but compensation for illness, one-half of which is preventable, is uneconomic. And yet this legislation, with its overload of preventable illness, will in all likelihood be enacted within five years unless society at large is intelligent enough to immediately proceed to the program of the prevention of disease.

These are a few of the basic principles that lie within the establishment of health departments as a part of the program of industrial relations. It behooves the employment manager, in fullest cooperation with the industrial physician, properly to interpret the problem to the employer and society.

Needless waste of lives and limbs through accidents is now an accepted working practice. The shameless loss from unnecessary illness, death, and invalidity should lead to a "health first" campaign, that in its infancy promises fourfold the results obtained from the "safety first" move-

ment. The latter was merely negative. It merely prohibited the man from injury—left him as good as he was. The industrial health campaign is positive,—constructive. It seeks not only to protect the worker against acquiring illness through plant neglect, but uses its best efforts to raise the health and standard of efficiency of every employee. In building up men, it builds up their energy and producing power. It builds sane minds in sound bodies. It releases new creative forces and adds to the total of wealth produced per man, which is the only sound basis of general wage increase. If employment managers wish to play a part in the most significant of world movements, they must have real understanding of the trend of industrial medicine.

Of what avail relatively are magnificent new buildings and equipment if the men working in them are not protected against the special health hazards that accompany the processes of manufacture? Of what avail sanitary floors if promiscuous spitting is permitted? Of what avail if sanitation and health hazards are well guarded, if the workers' housing and living conditions make for malnutrition and disease? If both the factory and the workers' housing and living conditions be admirable, he may still face the dangers of contagious diseases, bad foods, poor milk, impure water supply, and lack of proper sewage and waste disposal. It is apparent at once that we must find some way to avoid this vicious circle. It is within the power of the industries chiefly to lead this health crusade to a successful issue. No energy that they can put forth in their business will so promptly pay large dividends.

SOUTHERN RAILWAY SURGEONS HOLD ANNUAL ELECTION

The annual election of the Association of Surgeons of the Southern Railway, which took place recently at New Orleans, resulted in the selection of the following officers: Dr. Harry T. Inge, Mobile, Ala., president; Drs. William H. Armstrong, Rogersville, Tenn., Daniel W. Scott, McDonough, Ga.; Albert R. Wilson, Greensboro, N. C., and William T. Mathews, Greenwood, Miss., vice presidents; Miss Edith Foltz, Washington, D. C., secretary. The next annual meeting will be held in Washington.

REHABILITATION OF DISABLED WORKERS AND INDUSTRIAL CRIPPLES

The state of New Jersey at the last session of the legislature provided for the beginning of rehabilitation of industrial cripples. New Jersey is thus one of the first states to provide for this work, Massachusetts being the only other state which has heretofore made such provision. Dr. Fred H. Albee, of New York, chief of the surgical service at the United States Army General Hospital No. 3, Colonia, N. J., has been appointed chairman of the commission.

PROTECTING THE HEALTH OF SOFT COAL MINERS BY PREVENTION OF DISEASE

BY EMERY R. HAYHURST, M.D., PH.D., CONSULTANT, DIVISION OF INDUSTRIAL HYGIENE, OHIO STATE DEPARTMENT OF HEALTH, COLUMBUS, OHIO*

PRACTICALLY no statistics are available concerning sickness among soft coal miners. The bookkeeping of vital statistics has not extended that far. Some of the local unions and benevolent associations can supply certain limited statistics but these are too local to warrant drawing conclusions therefrom. Hospital statistics in mining districts are not representative, however complete they may be, since an unknown percentage of miners go to hospitals when sick. No insurance companies have to date taken out group policies covering sickness, among other disabilities, among miners.

We must rely chiefly on physicians in mining centers for the information desired. The experiences of physicians, scattered throughout the districts, particularly as to points on which they agree quite unanimously, are apt to be a fair index of the sickness situation.

Following is a summary of statements, covered by the questionnaire by which physicians were interviewed personally in mining communities:

1. *Diseases Rarely Found Among Miners.*—Certain diseases reputed to be prevalent among miners elsewhere or to be suspected, were found to be practically absent among soft coal miners. These are lockjaw, anthrax, glanders, hookworm, rat-bite disease, and nystagmus.

2. *Diseases Found Less Frequently Than Among Other Classes.*—Pneumonia (except among Negro miners where it seems to be more prevalent); tuberculosis (that which occurs is generally of a very slow progressive type, difficult to differentiate from miner's asthma); and venereal diseases. Mortality statistics (Illinois coal miners) on pneumonia and tuberculosis are not so favorable, however, as physicians' reports would indicate.

3. *Diseases Having the Usual Frequency.*—Acute rheumatic fever; afflictions of the upper respiratory tract, such as colds, tonsilitis, middle ear diseases, nose, throat and sinus affections; acute bronchitis; eye afflictions, although the communicable disease, trachoma, or "granulated eyelids," was frequent in some localities; skin affections; foot affections; deformities; nervous affections; hernias; varicose veins; other chronic diseases in general; and malaria. Epidemic diseases such as influenza, smallpox, and summer

diarrhoea are usually worse than in the usual rural villages.

4. *Diseases with Occupational Earmarks.*—Noted among these are "rheumatism," asthmatic afflictions, and disorders due to alcoholic beverages. The "rheumatism" is of the type unassociated with fever, called musculo-articular, of which lumbago is the chief form, and the so-called "sciatica" is next in frequency. Exposure to cool, damp atmospheres, drafts, the weather, and straining efforts on the part of men often not physically adapted for same, are underlying causes. The incidence of asthma is decreasing. Bad ventilation probably still plays a chief part in its cause, but the breathing of dust, and the susceptibility of men with weak hearts or other chronic diseases probably account for what asthma is found. Asthma rarely occurs in individuals under forty years of age. About one or two working men in a hundred are reported as asthmatics, and such conditions are a frequent cause of temporary absences. Alcoholism is exceedingly common, perhaps more so than in other industries, since it seems to be traditional among a considerable number of miners to take a day or so off after each pay for an alcoholic debauch. Less serious are dust plugs in the ears (of no consequence, but the cause of some temporary deafness); eyes flashed by electric short circuits; callousness on knees and sometimes elbows, hands and shoulders, mostly in "low coal" districts; "gassing" due principally to accidental breathing of white damp after blasting, fires, or explosions; and premature aging. This last is not a marked feature. There is some eye irritation due to sulphur (pyrites) dust.

General Summary of Diseases.—There is no reason for believing that the usual afflictions, aside from the respiratory system and the musculoskeletal system, are more frequent among miners than among other employes. In fact, as a class, they are probably healthier than the average type of factory worker. Top workers, exposed to the weather, are said to have more sickness than those in the mine. Sickness is much more rampant among the women and children in mining

*The second of a series of two articles presenting the conclusions derived from a survey of the health hazards and afflictions of coal miners in Ohio and Illinois, conducted by the two states jointly, in a cooperative arrangement, under the direction of Dr. Hayhurst, the author of the articles. The first of the two articles was printed in the June issue of MODERN MEDICINE.

districts than among the men. Alcoholism is far and away the chief bane. It is said to be on the decrease, explained by one physician as due to education, the increasing cost of alcoholic drinks, their frequent bad quality, and the extension of prohibition. Of the respiratory afflictions, chronic bronchitis associated with asthmatic symptoms, and often complicated by a chronic form of tu-

and quarrymen" in the country at large (Registration Area, 1909). This cause, however, is greatly in excess of the general average of all deaths from violence, which is 10.6 per cent for "occupied males" in the Registration Area, 1909. But one other class of workers, steam railway employees, surpasses miners in the high rate of death from violence. The marked excess in death from this cause to a large extent nullifies any favorable comparisons possible for deaths from other causes, as for instance, tuberculosis.

3. The tendencies in death rates for the chief causes of death, obtained by comparing the years 1916-1918 with the total period 1912-1918, were found to be as follows: deaths are increasing from tuberculosis, 106.5 vs. 99.4; cancer, 45.4 vs. 41.4; cerebro-spinal diseases, 70.0 vs. 57.5; circulatory diseases, 90.3 vs. 80.3; pneumonia, 118.5 vs. 98.1; cirrhosis of liver, 22.1 vs. 17.6; genito-urin-

ary (non-venereal) diseases, 61.0 vs. 50.5; and violence, 404.6 vs. 398.2. Deaths from the following show decreasing tendency: respiratory diseases other than tuberculosis, 26.9 vs. 42.6; and suicide, 29.3 vs. 31.9.

4. Malaria and typhoid fever were limited practically to southern counties in the state where sanitary conditions in regard to water supplies and sewage disposal are notoriously bad. All the remaining causes of death were fairly evenly distributed in proportion to the number of employees in each district.

5. The death rate of Illinois coal miners when compared with those of the entire United States Registration Area¹ is directly excessive, in spite of the number of deaths from violence, for the following afflictions: typhoid fever, 30.8 vs. 13.3; cirrhosis of liver, 17.6 vs. 12.3; and suicide, 31.9 vs. 14.2. The violence rate stands, 398.2 vs. 90.9.

It is hardly more than speculation to attempt to state the causes of the increase in mortality among Illinois coal miners. Violence as a cause of death has not increased materially. Working

The Graham Hospital, Centerville, Iowa, which is conducted by the United Mine Workers for its members. It is a fully-equipped, modern hospital, costing \$15,000. Medical and surgical service is furnished to members of the United Mine Workers and their dependents at the rate of \$0.75 a month per member. The institution was opened under this plan of assessments in August, 1918. The hospital staff is composed of Dr. G. G. Graham, Dr. Davis, and Dr. McFarland of Centerville; Dr. George Still of Kirksville, Mo., and Dr. S. L. Taylor of the General Hospital, of Des Moines, Iowa.

berculosis, is undoubtedly more prevalent than among agriculturists.

Mortality

Mortality statistics for Ohio coal miners have never been compiled. However, something may be gained from the result of figures compiled for Illinois coal miners where the state miners' organization keeps a careful record of each coal miner's death in its Death Claim Insurance Department.

There follows a summary of tables and statistics compiled for Illinois miners during the past summer (1918).

1. The death rate for Illinois coal miners has been constantly on the increase since 1912, the year for which the first figures were obtained. In that year the death rate per annum per 100,000 employees was 1,003; the death rate for 1917 was 1,167; and for the first six months of 1918, 1,185.

2. Violence, exclusive of suicide, constituted 36.8 per cent of the causes of death in 5,428 deaths among Illinois coal miners, from 1912 to 1918. This rate is 2.3 points less than for "miners

¹Mortality Statistics, page 19, 1916.

conditions are undoubtedly becoming better from year to year. Unquestionably, it cannot be charged to any single factor, such as alcoholism, which has been on the decrease throughout the period covered in the statistics; nor fatigue, since work hours have decreased while the assistance of blasting powder and machinery have increased; nor, with the exception of certain diseases like typhoid and malaria, has geographical distribution in the state anything to do with it. It is probable that a greater percentage are reaching the later age periods when deaths are more frequent, since the industry is not, in its present dimension, more than a generation old in Illinois: the same may be said for Ohio. It is probable also that a change in racial complexion, and in greater congestion of population and its attendant evils, without a corresponding increase in health supervision of housing and living conditions, are potent and basic factors.

How Miners Cope with Sickness and Death Hazards

Organized Medical Care.—Whereas in many other industries the management itself takes a leading part in organized medical care, such as sick and benevolent associations, this is not the case in the soft coal mining industry. Any organization in this line is supervised by the workers themselves. Whether any such organization whatever is present depends very largely upon (1) the size of the working force; (2) the location of the mine in respect to towns and cities; (3) the racial complexion; and (4) the interest manifested by the local union, which, in turn, depends largely upon the views of the officials of the same. Where a few men are employed, the existence of a benevolent association renders such service out of the question. Where the mine is located in a populous community, so many of the workers belong to secret lodges carrying sick benefits as seriously to interfere with a benevolent association. Where a majority of the workers are foreigners, strictly benevolent associations have a hard time to exist, since most of the foreigners prefer to belong to their own lodges, most of which, besides carrying sick benefits, are more or less religious in aspect. Where a benevolent association does exist, it is invariably optional with the men whether they belong or not, so that a considerable percentage of all workers are not members of the given local's sick benefit association.

It was the universal statement that practically all foreigners belong to some one or more of their foreign orders. They seem, indeed, more appreciative of such insurance protection than the native Americans. Many of them have received their initiation into community insurance schemes

abroad in the various countries from which they or their parents have come.

The usual forms of industrial insurance were everywhere present in the mining districts, through which children, in particular, are covered for funeral benefits.

Many of the miners, perhaps the foreigners more than the others, carried sickness insurance in several organizations, so that the statement was frequently made that a man while sick might draw more money in sick benefits collected than he did while well and at work.

Taking up a collection by passing around a paper or by "passing the hat" was a frequent procedure to help out some sick or injured worker. The amount of the collection usually depended on the case and too often on the popularity of the worker.

The great benefits derived from state compensation for injuries were everywhere evident.²

In contrast to the usual absence of sick benefit organization was the death benefit, really a burial fund, provided by most locals. On the occasion of the death of a miner, the local by special assessment or check-off at the mine, raised a fund varying in localities from \$25 to \$500. Usually a similar amount was raised for the death of a miner's wife, or other dependent adult, and a graded amount for children based on age of the child. At many larger mines the company also contributed \$25 provided the mine worked on the day of the funeral. This was arranged by agreeing that only the immediate friends of the deceased attend the funeral and the balance work. In Illinois, in addition to what given locals may do, the Death Claim Insurance Department of the state miners' organization pays the beneficiary \$250.

Status of Medical Services

First aid is generally well provided for at mines. Years of disastrous experience have resulted in bringing this about. Quarters for the injured or sick, however, are scarce except in two or three larger mining cities. There is no such thing as physical examination, although both workers and employers commended its advisability. If an epidemic breaks out in a mine or mining village, it is left quite entirely to whatever local health administration there is to cope with the situation. The fury of the present epidemic of influenza in mining districts was out of all

²At a home visited in company with a mining physician near Glouster, Ohio, was an instance in point: A miner, twenty-one years old, had been laid up twenty weeks with a compound fracture of the foot. He was about ready to go to work again. During this time he had received state compensation and, in addition, two collections from the men at the mine where he worked. These netted him \$28.30 and \$26.10. In the same house with him was his father-in-law, sixty years of age, an old miner, who had reared twelve children, and had mined all his life until "rheumatism" had compelled him to give up at the age of fifty-five years since which time he has had no income except one collection which the "boys gave him" of \$26.10.

proportion to most other districts and attests to the inadequacy of health supervision in them.

Inquiry shows that physicians tend to remain permanently located in mining districts; that they are very busy, and in normal times have a difficult subsistence, particularly during the months when the miners are not working. Though the workers are largely foreigners, the physicians are nearly all native Americans. Contract practice is almost a thing of the past. Even workers' organizations look unfavorably upon this form of medical service. A number of physicians visited said that they had discontinued contract practice as unfeasible and unsatisfactory. The prevailing fee rates are about the same in mining districts as in similar districts in the state of Illinois but rather less in the state of Ohio. The usual fees are: For calls at the house, \$1.50 to \$2; night calls, \$2 and up; office calls, \$1 and up, usually with medicine included; and confinement cases from \$10 up.

The ratio of physicians to population is about normal in Illinois, but the situation in Ohio shows a dearth of medical practitioners, being one physician to 2,016 of the estimated population in ten typical mining towns selected (the ratio through the United States is 1 to 739). It was found that this is not a war situation as very few physicians left mining districts in either state for direct war services. They were especially requested not to. Non-medical practitioners, such as osteopaths, chiropractors, christian scientists, etc., are few and far between. Licensed midwives are practically absent. Women practising midwifery, especially in foreign communities, are to be found here and there, but this practice is gradually abating as the foreigner is desirous of getting a "good doctor" on such occasions.

The trained nurse is practically an unknown person in mining communities; in fact, there are whole counties in both states in which there is no trained nurse, public or private. This is true, probably, of three-fourths of the mining counties. Many persons expressed the opinion that a community organization to assume part or all the cost of the services of a trained nurse would be advisable.

Diagnostic facilities are meager. An x-ray is most apt to be found of the various laboratory apparatus. Recourse for such facilities is usually had to large cities or the state laboratories. Such methods are reasonably prompt, but physicians said that there would be much more scientific medicine practised were diagnostic facilities more convenient.

Access to hospitals varies greatly. Some of the larger communities are fairly well provided for. Most communities, however, have no such provisions. The accessibility of the hospital means

much more to the physicians and patients' families and friends than it does to the patients, who may be transmitted easily enough fifty miles or more away, to a hospital. Many times physicians reported that to take a case to a hospital meant from one-half day to a day's time for each trip. Miners rarely resort to hospitals for sickness. The foreigner is more inclined to take advantage of hospitalization than is the native American miner. The miner's organization maintains its own hospital at West Frankfort, Illinois. It is a first-class institution and receives both miners and members of miners' families, the hospital expenses being met by the union. Also one of the larger companies maintains its own hospital at Zeigler, Illinois, which is thoroughly equipped and manned. A couple of cooperative hospital agreements between miners and hospitals exist in Glouster, Jacksonville, and Logan, Ohio. At Marion, Illinois, the unions also maintain their own mortuary and undertaking business, including ambulance, hearse, etc.

Organized Aid and the Physician

About 90 per cent of the foreign type of miners belong to one or more sick benefit societies and about 50 per cent of the native miners. The usual fraternal societies are strong among the latter, hence sickness insurance already exists to the above extent in the mining districts. The weekly benefits paid run from \$2 to \$10 or \$12, the vast majority paying \$5 per week. As a man may belong to several, he may of course derive a fair income during sickness. The physician is almost entirely dependent upon the returns from these sick benefit societies for his fee. He fills out weekly a certificate of illness and, in turn, gets some or all of his fee. These financial transactions were commented upon by physicians as often uninviting. Much time is spent in filling out various certificates. A couple of physicians in an Illinois town stated that, between them, at least eight hours per week were spent in this filling out of a multitude of sick benefit certificates. In practically all cases the physician makes no charge for this service, although here and there a charge of from 50 cents to \$1 was made for each certificate. Many physicians commented upon the evident attempts at malingering, particularly where a workman was over-insured by carrying policies in several societies. Most physicians stated that they would like to see some other system adopted in place of the present sickness insurance relationships; for instance, the submission of bills directly to the benefit society, and the dealing with a limited number of societies per patient. The physician feels safer as to his own fee when he is dealing with an organized

body such as a lodge or society than when he is dealing directly with many of the patients who seek his services in mining communities.

The general average of collections is about 75 per cent of the fees charged, in normal times, although it is somewhat better at present. Some physicians reported as low as 50 per cent collected; others claimed collections as high as 90 to 95 per cent. Collections were better in isolated localities as a rule. The continual shifting of labor (labor turnover) is also blamed for the loss of many accounts. Slow pay is a bad feature in normal times. Workmen's compensation for accidents has resulted in better collections and more prompt demand for physicians' services in case of treatment for injuries.

Quackery flourishes practically without limitation in mining communities. The prescribing druggist and grocerman is a fairly common occurrence, also. One physician in an Ohio town stated that a prescription of a cousin of his, a physician who had been dead twelve years, had become the general property of the neighborhood, and whenever persons had something resembling the original sickness prescribed for, they went to the given drug store and asked to have Dr. So-and-So's prescription Number such-and-such filled for them.

The old-time street medical vender has quite disappeared. The miner patronizes the various types of nostrums very liberally. This is undoubtedly due to several factors such as the extensive advertising of the same, lack of ready funds with which to pay for legitimate treatment, and the desire to try a cheap substitute first. One cannot help gaining the impression that enough money is thrown away in mining communities on unscientific medical care to more than foot the bill if the whole thing were put on an organized sickness insurance basis, to say nothing of the saving in the amount of sickness and preventable deaths.

Twelve Suggestions for Improving Health Conditions in Mining Communities

1. There should be a housing survey.
2. There should be a medical service survey.
3. More aid should be extended to the respective state mining departments, particularly in the nature of hygienists' services.
4. There should be a standardization of the many existing forms of health insurance which now prevail.
5. All employees should be required to carry health insurance and optional membership done away with.
6. More Americanization is necessary in foreign districts.

7. More hospital, dispensary, nursing, and diagnostic services are required.

8. Physical examinations, preferably by state employment agencies, should be compulsory for employees at the time of hiring and after returning from an absence due to sickness or injury.

9. In any standardization of sickness insurance a free choice of physician should be allowed and remuneration placed on the merit basis, i. e., so much for a given service rendered. A large part of medical service could be fee-scheduled in much the same way as certain county medical societies at present publish their service rates.

10. Arrangements should be made for the services of specialists and experts, both for business management and for the insurance features, as well as for treatment services.

11. A certain part of all sickness insurance premiums paid should be definitely set aside to provide for the application of sanitary science, the latter to be under general supervision of the state health department.

12. All persons or services having to do with sanitation or medical care should be licensed as a check against unscientific methods.

THE JOURNAL OF INDUSTRIAL HYGIENE

The *Journal of Industrial Hygiene* made its first appearance in May, 1919, under the editorship of David L. Edsall, A.M., M.D., Harvard University; A. F. Stanley Kent, A.M., D.Sc., editor for Great Britain; Thomas M. Legge, honorary consulting editor. The following associate editors are named: W. Irving Clark, Jr., M.D.; Alice Hamilton, A.M., M.D.; Emery R. Hayhurst, A.M., Ph.D., M.D.; Yandell Henderson, Ph.D.; William H. Howell, Ph.D., M.D., Sc.D., LL.D.; Frederic S. Lee, A.M., Ph.D., LL.D.; Harry E. Mock, M.D.; J. W. Schereschewsky, M.D.; and C.-E. A. Winslow, M.S., A.M., Dr.P.H. The publication is under the managing editorship of Cecil K. Drinker, M.D., and Katherine R. Drinker, M.D.

The first issue contains a review of industrial medicine and surgery by Harry E. Mock, M.D., Lieut.-Col., M.C., U.S.A.; a treatise on lead poisoning in American industry, by Alice Hamilton; a study of the problem of fatigue by Reynold A. Spaeth, of Johns Hopkins University, and a study of the medical aspects of telephone operating made by Anna G. Richardson, M.D., physician of the New England Telephone and Telegraph Company, Boston. The number is especially complete as to abstracts and bibliography of related subjects.

In the June issue the value of this journal in its special field is shown by the range of subjects treated. "The Use of Army Gas Masks in Industry" is presented by A. C. Fieldner, Major, Chemical Warfare Service, U.S.A.; "Human Health and the American Engineer" by George C. Whipple, S.B., Harvard University; "Chip Fractures of Terminal Phalanges" by William R. Hurley, M.D., Bethlehem Shipbuilding Corporation, Quincy, Mass.; "Inorganic Poisons, Other than Lead, in American Industries" by Alice Hamilton, M.D.; and "Medical Inspection of Factory Employees" by Maynard A. Austin, M.D., surgeon and medical director, Remy Electric Company,

Anderson, Ind. The book reviews and announcements are calculated to give the desired information on the broadening activities of industrial medicine.

AMERICAN ASSOCIATION OF INDUSTRIAL PHYSICIANS

The annual meeting of the American Association of Industrial Physicians and Surgeons preceded the formal opening of the American Medical Association meeting and filled one full day, June 9, with solid discussions. President Harry E. Mock, former physician to Sears, Roebuck & Co., delivered an address on "New Developments in Industrial Medicine and Surgery," which appears in full in this issue of MODERN MEDICINE. "Syphilis, an Inestimable Factor in Industrial Inefficiency" was treated by Capt. E. A. Oliver, M.C., U.S.A. "Is War-Time Surgery Applicable to Industrial Surgery" was handled by Dr. John Moorhead, surgeon of the Interboro Rapid Transit Co., New York. "Strains of Back, an Accident or Disease" was the subject of a paper by Lieut.-Col. R. B. Osgood, M.C., U.S.A. "Conservation of the Vision of the Industrial Worker" was introduced by Dr. Wm. W. Blair, Pittsburgh. A frank discussion of the "National Program for Industrial Hygiene and Medicine" was led by Col. A. J. Lanza, United States Public Health Service.

During the business meeting in the morning it was decided to appoint a legislative committee, a publicity committee, and a committee to draft a curriculum for a uniform course in industrial medicine and surgery which may be given at medical colleges. There was some discussion over this latter suggestion inasmuch as some medical men connected with the faculties of medical colleges felt that medical schools on the whole would find it impossible to add to their curriculum.

The outstanding features of the afternoon session were a remarkable paper by Dr. John Moorehead, surgeon of the Interboro Rapid Transit Company of New York, and the appeal of Dr. C. D. Selby of Toledo, Ohio, for a continuation of the division of industrial medicine and hygiene of the working conditions service of the United States Department of Labor. Dr. A. J. Lanza, chief of that division, in his address, which preceded Dr. Selby's appeal, explained in considerable detail the investigations made by his division and how it was on a large scale helping industries in all parts of the country better to protect the health of the men and women in their employ. Dr. Selby made his audience feel that to abolish Dr. Lanza's division of the labor department, as threatened by the unwillingness of the present Congress to appropriate the necessary funds, would be nothing short of a national calamity.

Dr. Selby felt that the practice of industrial medicine was beginning to do much to stabilize labor conditions in the plants into which it has been introduced.

During the morning discussion, the question of defining what constituted a traumatic hernia brought out the importance of the labor problem which touches all branches of industry at the present time. Dr. A. W. Colcord, of the Carnegie Steel Company, read a resolution which defined traumatic hernia as hernia which occurs only when there is a definite laceration of the body-wall together with no evidence of a hernial sac. Dr. Colcord felt that employers were being greatly imposed upon by employees who wished to collect damages under the workmen's compensation act for injuries the original causes of which date back previous to the time of employment.

Dr. Francis D. Patterson, of the Department of Labor

and Industry of Pennsylvania, in characteristically vigorous and amusing phraseology roundly criticized "the constitutional effrontery which characterizes the legal profession on every occasion" in the attempt of lawyers to diagnose the conditions which lead to hernias, and suggested that the association should place itself on record as suggesting that a member of the medical profession be placed upon every industrial accident board in order that his advice might be available in questions requiring an expert medical opinion. "There isn't an employer throughout the land," he added, "who hasn't bought an old hernia and paid a darn good sum for it."

Dr. Otto Geier, of the Cincinnati Milling Machine Company, remarked that, since labor has become so favorably inclined toward the whole proposition of industrial medicine, it might not be wise to antagonize the workers and suggested that perhaps it would be better to ask the American College of Surgeons, which is not in immediate contact with the human side in industry, to define traumatic hernia for the benefit of workingmen's compensation boards.

Discussions were given by Major Warren Walker, M.C., U.S.A., C. A. Lauffer, chief surgeon, Westinghouse Electric Co., Pittsburgh, Dr. C. G. Farnum, chief surgeon, Avery Company, Peoria, Ill., Dr. James Boardly, Jr., Baltimore, Dr. J. B. Curry, American Thread Co., Holyoke, Mass., and Dr. Otto P. Geier, Cincinnati.

The following officers were reelected: President, Lieut.-Col. Harry E. Mock, M.C., U.S.A., Division of Reconstruction, Washington; first vice-president, Dr. Thomas R. Crowder, Pullman Co., Chicago; second vice-president, Dr. Otto P. Geier, Cincinnati Milling Machine Co., Cincinnati; secretary-treasurer, Dr. Francis D. Patterson, Department of Labor and Industry, Harrisburg, Pa.; assistant secretary-treasurer, Miss Pauline Gunther, 122 So. Michigan Ave., Chicago. Directors were elected as follows: Dr. W. Irving Clark, The Norton Co.; Dr. R. W. Corwin, Colorado Fuel & Iron Co.; Dr. C. E. Ford, General Chemical Co.; Dr. G. L. Howe, Eastman Kodak Co.; Dr. J. E. Mead, Ford Motor Co.; Dr. F. C. Warnshuis, Pere Marquette R. R. Co. The directors held over are: Dr. A. W. Colcord, Carnegie Steel Co.; Dr. Judson C. Fisher, Globe Indemnity Co.; Dr. E. B. Hanna, Cadillac Motor Co.; Dr. H. P. Hourigan, The Larkin Co.; Dr. D. B. Lowe, B. F. Goodrich Co.; and Dr. J. W. Schereschewsky, U. S. Public Health Service.

INDUSTRIAL AND TRAUMATIC DEFORMITIES

By far the most essential consideration in the surgical treatment of industrial casualties, injuries, or fractures, is in the careful application of the principles of modern asepsis, since every such casualty is a potential deformity, and infection is the greatest factor in producing deformity—to summarize the remarks of Walter G. Stern, M.D., F.A.C.S., Cleveland, surgeon, in an address delivered at the recent Columbus meeting of the Ohio State Medical Association. He spoke on "Industrial and Traumatic Deformities, Their Prevention and Treatment."

"Modern orthopedic surgery," he stated, "would hold that all casualties, injuries, or fractures are potential deformities and that the principles of reconstruction must be applied with the first dressing and continuously carried out until complete functional recovery has been attained. While the present day military needs have brought out little that is new, yet it has standardized our practices and focused attention upon the necessity for functional care and rehabilitation."

"General surgery has long been contented with excising

or repairing the damaged tissues, and a case was considered cured when the wounds no longer required dressing. Orthopedic surgery is satisfied only when the injured man is able to make as much functional use of the damaged part as is humanly possible."

Dr. Stern, who is orthopedic surgeon to Mount Sinai and St. John's Hospitals, Cleveland, Ohio, and to the Elyria Memorial Hospital and Gates Hospital for Crippled and Deformed Children, Elyria, Ohio, declares that infection is to be avoided at all hazards and at all costs.

The prevention of infection is accomplished "by scrupulous care during the first aid and by refraining from all unnecessary operation surgical intervention until the time comes when better circulation has been reestablished and the damaged parts more immune to irritation and infection. It will usually be sufficient for the first aid to apply a sterile emergency dressing and firmly bandage the injured part to a supporting splint or brace and transport the patient to more favorable surroundings—hospital or doctor's office, when possible—where the *real* 'first aid' should be given. This should consist of a thorough cleansing and disinfection of the part, the debrissement of all tissues whose vitality is manifestly lost, careful haemostasis, the 'toilet of the wound for tomorrow's needs,' loose suturing for the approximation of the soft tissues, the complete reduction of fractures—usually under anaesthesia—and finally the proper fixation of the injured member in the position most suitable for combatting any deformity which might arise."

A resumé which Dr. Sharp prepared as a review of his conclusions, sums up the argument and further states:

"Extensive use should be made of all the modern forms of extension, Steinman pin, Calliper tongs, Balkan frames, Thomas splints, etc. All fractures should be radiographed for study and record.

"After the danger of infection has passed, corrective operations can be safely performed.

"Closed fractures are not to be unnecessarily opened up. End to end apposition of bone fragments is not a '*sine qua non*' for a good functional.

"Ununited and malunited fractures, deformities, scars, and defects can be overcome by well chosen measures.

"The benefits of hydro-, electro- and mechano-therapy, massage, active and passive exercises, and functional re-education are to be made available for the injured worker in order to rehabilitate him back into industry in as short a period and in as good physical condition as possible."

PREVENTABLE INJURIES TO THE EYES

Carelessness is chiefly responsible for a major proportion of the many eye injuries that occur each year, and blindness as well, says Walter N. Sharp, M.D., who has written a discussion on "Eye Injuries in Relation to Industrial Organizations and Insurance," which is published in the May issue of the *Indianapolis Medical Journal*.

The carelessness may be on the part of the individual; again it may be an employer's carelessness in not providing proper safeguards against eye injuries, or it may be the carelessness of an attending physician in doing less for the patient's welfare than he should have done in a fair attempt to conserve the sight of the injured eye.

Dr. Sharp presents his own recent records of 509 cases of injury to the eye, as follows:

Glass from broken lens worn for protection.....	1
Glass in the eye from other sources.....	4
Corrosive substances: lime, sal soda, acids, kerosene oil, cyanide of potash, carbide, live steam, hot solder, hot glue.....	52

Steel and iron in cornea.....	103
Emery in the cornea.....	118
Other substances: stone, brick, concrete, brass, lead and others, the composition of which was not known	201
Penetration of the eyeball by wire, 3; nails, 8; steel, 14; glass, 1; copper, 2; stone, 2.....	30
	509

About 80 per cent of these accidents were received in industrial occupations.

Dr. Sharp writes, in part:

"The majority of injuries of the eye received are apparently mild and insignificant ones, but if they are not properly attended to they become serious. I refer principally to foreign bodies in the cornea. These bodies are composed principally of minute particles of emery, though small particles of iron or steel, rust, etc., may be lodged in the outer layer of the cornea. Of all bodies, emery is the most difficult to remove nicely, as it flakes and leaves a stain which must also be removed as this is oftentimes quite as irritating as the original body itself. These bodies usually lie in the epithelium or outer layer, though occasionally they are embedded much more deeply. They must be removed by gently pricking about them and lifting them out instead of scraping them out, for by the latter method, much more tissue is destroyed and there is much more liability to infection; besides this, destruction of the corneal tissue below the epithelium often results in a loss of transparency.

"As a rule, foreign bodies in the cornea do not affect the visual acuity unless they are embedded over the pupillary area.

"I have seen cases in which foreign bodies were unskillfully removed, large areas of epithelium scraped off and ulceration followed, resulting in complete loss of vision. Such a case came under my observation a few years ago. The man was sent from an adjoining city where he had been treated, to the city hospital. The whole center of the cornea was in a state of purulent ulceration as a result of unskillful treatment following the presence of a small foreign body.

"Pieces of magnetic metal embedded in the cornea can often be removed by an electro-magnet without any injury to the cornea except that originally produced by the foreign body.

"Large pieces of metal graze the cornea in some cases and produce more trouble than a body embedded in the outer layers.

"Why do we have so many eye injuries? When we sum up the thousands of minor injuries that only physicians and liability companies know of, and the hundreds of more serious accidents brought to trial before the Industrial Board we need use but one word in answering this question—carelessness.

"With some people, the preaching and teaching of conservation of vision 'goes in one ear and out of the other.' They seem to pay little heed to the preservation of the function of vision, which is one's greatest asset. It always seemed strange to me that an employer was responsible for the carelessness of an employee, especially when every means of precaution to avoid accident had been taken. In fact, he is not responsible.

"According to reports in the *American Journal of Ophthalmology* there were in the United States for twelve months previous to June, 1917, 59,436 accidents to the eye which were about 8.3 per cent of all industrial accidents. That journal says that approximately 15,000 persons in the United States are blind to-day as a result of injury in industrial occupations, and that the maintenance of these blinded artisans during the remainder of their lives will cost nearly ten million dollars, which expense will fall in large part on relatives, the community, or the state."

There is nothing mysterious about the prevention of disease, declares the United States Public Health Service. Clean homes, clean hands, clean food, clean teeth, clean milk, pure water, fresh air, sanitary privies, war on flies and mosquitoes cost but little, but work wonders in preventing sickness.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C. E. A. WINSLOW, DR. P. H., Editor

THE CO-RELATION BETWEEN POVERTY AND DISEASE

THE sessions of the Section on Health of the National Conference of Social Work at Atlantic City in June were entirely devoted to a single topic—the relation between poverty and disease. An unusually able and well-informed group of speakers discussed the effect of a low standard of living upon food and housing, infant mortality, tuberculosis, venereal diseases, and industrial diseases, and upon the adequacy of general medical and nursing care. Results of recent investigations were presented, of much importance to all who are concerned with the protection of the Nation's health.

The discussion was remarkably free from facile dogmatism. Speakers on infant mortality and venereal disease and malnutrition, in particular, emphasized the complexity of the problem and pointed out that racial and social factors may often in an individual case be more important than economic ones. The infant death rate, for example, is frequently higher in native-born and comparatively prosperous population groups than in much poorer neighborhoods inhabited by foreigners among whom breast-feeding is a general custom.

The fact that variable A may sometimes produce a greater effect than variable B, does not, however, indicate that B is a wholly negligible factor. There can be little doubt that, when other things are equal, poverty is correlated with a high death rate. In the Johnstown survey¹ it was found that the infant mortality in one ward was 271 deaths per 1,000 births, against 134 for the city as a whole, and fifty for the ward which showed the lowest rate, and the explanation is that "This is where the poorest, most lowly persons of the community live—families of men employed to do the unskilled work in the steel mills

and the mines." A report by Anna Rochester of the Children's Bureau of similar studies conducted in Baltimore reveals essentially similar results. Dr. Seydenstricker and his associates in the United States Public Health Service² find that among cotton mill operatives in South Carolina the rate of disabling sickness was 70.1 per 1,000 among families with monthly income equivalent to less than \$12 per person (on an adult male unit basis); with an income between \$12 and \$14 the rate was 48.2 per 1,000; with an income between \$16 and \$20 it was 34.4; and with an income of \$20 or more it was 18.5 per 1,000.

We may conclude from these figures and from many similar investigations that poverty and sickness are closely correlated. We cannot conclude that the poverty is responsible for the excess of sickness, for, in many instances, the relation of cause and effect may be reversed. Usually people do not live in the poorest quarters of a city or work at its underpaid employments by choice or by accident. In general, and on the average, in such districts and such employment is found a concentration of tuberculosis stock, of alcoholic stock, of feeble-minded stock—poor protoplasm and a bad environment supplementing each other in a vicious circle.

No one can perhaps tell just how far poverty in such cases is the real and effective cause of the failure to achieve and maintain a normal standard of physical health. It is abundantly clear in specific instances that poverty is at least one direct factor in the causation of disease,—as was pointed out at the Atlantic City conference, that many people are sick and many people die because they are poor, not only in starving Russia and devastated Belgium but in America as well. The mother who is forced by economic necessity to work in a factory instead of nursing her baby, the victim of tuberculosis who, because of economic pressure, goes on working long after he should have been in a sanatorium,—these are all too familiar figures to the public health worker.

¹ Publication No. 9, United States Children's Bureau, Washington, D. C.

² Public Health Reports, November 22, 1918.

General Gorgas, it will be remembered, was convinced by his experience at Panama that the best way to combat even pneumonia was by raising the standard of living for the individual and the family.

That the standard of living of American families is to-day in many cases inadequate for the maintenance of physical health was made abundantly clear by the data presented at the Atlantic City conference. The studies of the United States Bureau of Labor Statistics conducted under the direction of Royal Meeker and summarized elsewhere in this issue of MODERN MEDICINE have thrown a flood of light upon the subject. It appears from these studies that, while the average of wages has risen over 50 per cent during the past five years, the cost of the necessities of life has risen in a considerable higher ratio so that for the average workingman what the economist calls "real wages"—wages measured not in dollars but in their equivalent of food, clothing, and housing,—have fallen since 1914. It was true in 1914 that a considerable proportion of families had incomes inadequate for the provision of good housing and good food and totally inadequate for the provision of adequate medical and nursing care. According to the Bureau of Labor Statistics there must be even more families in this condition today.

If an initially normal family cannot gain a livelihood adequate for its minimum physical needs there is evidently a problem of social readjustment which our nation must face as a fundamental of post-war reconstruction; but what shall be said of the family which on account of inherent physical or mental defects is unable to reach a minimum level under a wholly fair and equitable basis of compensation? There are but two alternatives, since the moral sense of mankind repudiates the rigorous application of the principle of unhindered natural selection. The combination of defective protoplasm and crippling environment may be allowed to accomplish the major portion of its work, and society may then salvage what it can from the wreck by some form of institutional relief; or, social energy and community funds may be applied in preventive fashion to make good the deficiencies in the beginning. The latter seems likely to prove more economical in the long run.

The immediate result of the Atlantic City meeting was the appointment of a special Committee on the Standard of Living Essential for the Maintenance of Health. It is hoped that this committee will be organized with a membership of economists, statisticians, household administrators, dietitians, and housing experts sufficiently

eminent to command general confidence; and that next year it will be able to report an approximate minimum for the family budget, adjusted so far as necessary to varying geographical and social conditions and so connected with the index of price levels that it can be utilized on a sliding scale for some time in the future. The formulation of such an authoritative standard should stimulate each locality to determine what proportion of its population is actually below the limit of safety; and it should prove of material value to the public health worker in his attempt to deal with those special factors in the health problem which have their roots in poverty. EDITOR.

SUCCESS OF PREVENTIVE MEDICINE

"FEW realize how crucial has been the test of preventive medicine in the war just finished. Appalling as has been the number of battle casualties, the death rate from disease has been held down as never before. The statistics available show conclusively that the great scourges and plagues of former armies have been held in check: that is, typhus fever, cholera, recurrent fever, typhoid, seury and malaria, and, not least important, smallpox. Influenza with pneumonia, occurring in an epidemic sweeping over the eastern and western hemispheres, has been the epidemic that has baffled medical science and stands out with startling distinctness as the one uncontrolled epidemic. The death toll of pneumonia has almost equaled the battle casualties of those killed and dying of wounds in the American army. In spite of the failure to control influenza and pneumonia, this is an extraordinary record of disease control, and never, in any previous war, has the knowledge of medical science and sanitation, and the application of this knowledge been able to accomplish so much. We saw typhoid start as an epidemic in Belgium, in 1914, spread with its old-time fury among the troops at that point, and then we saw it conquered by sanitation and vaccination. We have seen typhus spread with terrible fury in Serbia and in Austria, we have seen typhus and recurrent fever break out in Russia, and again through the knowledge that these diseases are carried by body lice the epidemics were controlled. . . . To appreciate fully the meaning of this result of preventive medicine and what the American medical profession has accomplished, let us study the battle casualties and disease rates of former wars, and, by this contrast, appreciate the achievement."—Alexander Lambert, presidential address, seventeenth annual session of American Medical Association, Atlantic City, N. J.

HOUSING AND HEALTH

BY JAMES H. McBRIDE, M.D., PASADENA, CALIFORNIA; MEMBER CALIFORNIA STATE COMMISSION OF IMMIGRATION AND HOUSING; PRESIDENT AMERICAN NEUROLOGICAL ASSOCIATION*

MAN is naturally an outdoor animal. Relative to his entire history, his civilization is an achievement of yesterday and he is still trying in a bungling sort of way to adjust himself to its complex conditions. His bad housing, his diseases, his injurious occupations, and his criminality show how far he has yet to go before he can make any just claim to ideal morals or sanitation.

The sanitary importance and social value of good housing have been appreciated only within recent years. The house a man lives in, with its material and human environment, is immediately related to his health, his character, and the quality of his work. It is largely a measure of what he is and what he can do, for we find that people may be saved or killed, that they may be made honest or criminal, that even the human interests of a nation may be promoted or harmed by the conditions that are summarized in the word housing. From the viewpoint of physical stamina, civilization has made a sorry failure of its care of the race, for if our knowledge of wild men is an indication of the kind of men that preceded civilization, instead of gaining, men have lost in physical vigor since they have lived in houses.

Longevity Not Really Increasing

We have not been free from a certain amount of self-deception in regard to the supposed increase of the length of life during the past century, for the increase has been largely due to the lessened death rate of infancy. Men do not live as long after fifty as did their grandfathers. We are saving more of the babies, but adults are breaking down from disease of the internal organs.

There are numerous indications that the race is not gaining in physical stamina, in ability to stand the increasing stress and adverse condi-

WHY GOOD HOMES ARE NEEDED

The vital part which housing conditions play in determining the health and hardihood of a people is convincing evidence of the necessity for improving the standards of housing in crowded industrial centers and in the eongested quarters of large cities.

The measurable benefits in health and prosperity resulting from the projects for better housing which have been carried out in this and other countries is proof enough of the sound economic reasons for insistence upon better housing.

Unhealthful housing accommodations exist in country districts as well as in cities.

tions of civilized life. There are many causes for the physical degeneracy that is seen today, but one of the chief causes is the houses men live in and the general conditions that are connected with house life. Housing is one aspect of the complicated conditions that affect the health of men individually and, also, that of communities. It is only recently that the evils of bad housing and their extent have become ap-

parent, and we are but now in the pioneer stage of remedial work. The growth of city slums where is found much of the wreckage of our so-called civilization, is largely in proportion to the size and wealth of the cities. As palaces multiply on the avenues, slums spread like a pestilence in abandoned districts, and from the latter comes an increasing multitude of diseased and defective humanity.

The Curse of Congestion

Land congestion in cities, tenement house evils, overcrowding, disease, and human degeneracy are by no means modern. The tenement is an old offender. Tyre, Babylon, and Rome had it and there is no evidence that these cities made any intelligent attempt to remedy the evils that resulted from the tenement. According to Eugene Jager, tenements were introduced into Rome 445 B.C. In the time of the Emperors there were 46,000 rented buildings and 18,000 private houses in the city of Rome. Owing to lack of transportation, land was high, rents were exorbitant, and there resulted much crowding of buildings. Sulla, whose fame seems to have been out of proportion to his income, lived on the ground floor of a tenement. Because of high rent, a dethroned king of Egypt lived in a small apartment in a top story. He was at least more fortunate than other kings who were then living in Roman dungeons. As land became more expensive, buildings rose to many stories, and, later, Augustus found it necessary to limit their height by royal decree.

*Address delivered before forty-third annual meeting, American Academy of Medicine, Atlantic City, N. J., June, 1919.

Martial complained that he had to write his poetry in a tenth-floor room and that he had to climb two hundred steps to get to it. Montelius, the teacher of Horace, had to live in an attic and paid high rent. These rooms were small, with low ceilings, no window, and no ventilation.

Rent Reduction a Remedy

Many attempts were made to reduce rents, or to remit payment for a year, but the rich tenement owners opposed these proceedings and won

places from which comes the larger proportion of tuberculosis. In the Johnstown investigation of infant mortality the death rate of infants was found to be directly related to housing conditions, and these, of course, depend upon the mother's or the father's wages. Given the income of a number of families, one could predict the approximate infant death rate. The death rate was higher in dirty homes than in those that were clean, and still higher in those that were both dirty and damp.

Crowding and Sickness Coincident

In a certain American city of 500,000 population, a number of pin maps were made to indicate the location of cases of sickness. It was found that the pins put in the maps to show the location of insanitary and overcrowded homes went in at the same places as the pins for sickness. In the well-housed districts, the death rate was thirteen per 1,000, in the badly housed it was nineteen per 1,000. The maps also showed that crime, delinquency, drunkenness, and insanity occurred chiefly among the badly housed.

This is the tale of a single city; but the conditions are duplicated in hundreds of other cities. The facts show, though imperfectly, the price that any city must pay for the neglect of the decencies of its housekeeping and the consequent wastage of its human values. The money spent for charity, for hospital care, for crime, pauperism, etc., would, in a few years, rebuild these degenerate districts and restore to industry and decent living those who are now a deadweight to the community and a menace to its good order and its morals.

Slums Not in Cities Only

Bad housing is not confined to cities; it is found in villages and on farms. Health authorities say that much of the typhoid fever of the cities is contracted in villages or on farms, the victims of the infection going to the city before or immediately after the development of the disease.

There are slums in the country because slum means dirt, neglect, poor ventilation, poor food and clothing, and overcrowding; and all this is not infrequently found on farms, where the old oaken bucket of fond memory may dip contaminated water from the well, and where cows that "wind homeward o'er the lea" give milk that from dirty hands, may carry typhoid or tuberculosis.

The Wisconsin Anti-Tuberculosis League found that in some country districts the death rate from tuberculosis exceeded that of Milwaukee, the largest city in the state. In Minnesota it was found that there was much overcrowding on

One ill-kept room that was used as bedroom, kitchen, pantry, and parlor.

in every contest. Julius Caeser, during his reign, decreed a universal reduction of rents. Cicero, who had houses to rent, spoke out in quite modern language. He said: "They are to live free on the prosperity of another . . . what is that but to take away his property from him in order to give to a stranger." Poor transportation and high prices of land made tenements possible. The conditions that produce this state of affairs in our modern cities, produced it in Rome.

Every year in the United States the following average number of deaths from communicable diseases are reported, and this is only a partial list:

Measles	12,000
Whooping cough	10,000
Scarlet fever	9,000
Diphtheria	18,000
Tuberculosis	150,000

These are house diseases in the sense that the house is their usual breeding place though it is, of course, quite possible to contract them or any disease out-of-doors.

Tuberculosis is a house disease. The bacilli that cause it live in dark corners, in damp houses, in ill-ventilated homes, in filthy homes, in overcrowded homes, in cheerless homes, in homes of poor food and scant clothing—these are the

farms, and that as much tuberculosis existed among these people as in the overcrowded quarters of cities. It was found that four, five, and sometimes nine people slept in one room of a farm house, while there were several rooms in the house vacant. Presumably this was for the purpose of saving fuel.

Dr. Bashore, inspector for the Board of Health of Pennsylvania, has found similar conditions in the country districts of that state. One house, during a period of forty-nine years, had sheltered six different families and every family had one or more cases of tuberculosis while in the house. This was a large, pleasant-looking farm house, but lack of intelligent care had made it essentially a pest house.

Death Rate in Degenerate Houses

In Finsbury, a crowded quarter of London, a million people, chiefly families, live in houses of two rooms or less. The sickness occurring in this quarter is in direct proportion to the overcrowding; given the room space and size of families one could predict approximately, as at Johnstown, what the death rate would be. Relative to the kind and amount of room furnished, the owners of degenerate houses receive a much larger rent

is giving a prize to the owners for overcrowding the unfortunate, and for maintaining that which is a menace to the health of the neighborhood, while their competition with the honest landlord is a standing injustice.

Disease Stalks From Slums

People who live in decent houses come in contact in many ways with those who live in disease-breeding hovels. These latter come as messengers to doors of healthy homes. They help in canneries where fruits may be infected; they handle foods that are sold in the market; they make wearing apparel; the traveler may handle after them towels, dishes, faucet handles, and when infected, wonder where the infection came from. The very poor who are badly housed are shorter in stature and weigh less than the prosperous members of the community. Young people living in overcrowded quarters are stunted in growth and do not develop so well mentally as those under better conditions. The vital resistance is lowered and there is not only more sickness among this class but it is more serious. We should expect to find what we do find in cities like Glasgow, London, or New York—that in the slum districts the people are dwarfed physically and are more likely to be mentally degenerate.

Physical degeneracy, due to bad housing conditions, has been observed in all cities where investigations have been made. Children living in one-room tenements are shorter and weigh less than those living in two-room tenements; and when families have three rooms or more the height and weight of children are greater. It is said that two-thirds of the cases of delinquency among Chicago children come from the badly housed districts, and an equal proportion of the shiftless mothers and deserting fathers come from the same districts. Horsfalls says that in England the chief cause of poverty is bad housing. Of 1,000,000 British mothers 95,000 lose their babies before the age of one year. A commission reported that the two major causes are poor food and wretched housing.

The Real Cost of Crowded Quarters

There are about 30,000,000 wage earners in the United States. As nearly 10 per cent of their time is lost in sickness, and as it appears much of this is due to bad housing, the cost of the latter to this class alone mounts to the region of ten figures. The housing problem in the city is largely a question of finding a home for the wage earner. Good housing for the wage earner is rendered difficult because of the cost of land and building.

A Picture with a Moral. The best type of citizenship cannot thrive where the years of childhood are spent in unhealthful conditions.

than do those who rent sanitary houses. The honest and careful landlord suffers from competition with the man who takes advantage of the misfortunes of the very poor and charges high prices for slum quarters. These degenerate houses, originally built for one, two, or three families, are later occupied by twice, or even five times as many families. The rent of the buildings is relatively high and the repairs a mere fraction of that of decent houses. The community that allows such buildings to be occupied

J. G. Schmidlapp, of Cincinnati, who has devoted much attention to building houses for wage earners, has suggested the following weekly budget for that class: One day's wages for rent; two days' wages for food; one day's wages for clothes; one day's wages for extras; including light and fuel; one day's wages for profit and pleasure. He says the disposition of this last day determines whether or not the wage earner is to become an investor, as most of the fortunes of this country began in the saving of a few dollars per week. Mr. Schmidlapp says the unskilled wage earner should be able to procure a home for not more than \$1,200, with at least five rooms, one of which should be a bathroom. The often repeated charge that the poor will use a bathroom for a coal bin has been abundantly disproved by the experience of Mr. Schmidlapp, General Sternberg, of Washington, and Mr. White, of Brooklyn.

Housing Laws and Public Health

In every city in the world where sanitary homes have been provided for the workers, the death rate has been lowered. New York City furnishes an illustration of what housing laws may do in improving the public health. The first tenement house law of New York City was passed in 1867. At that time the death rate was thirty-five per thousand. Five laws have been passed down to 1910, each law more stringent than the previous one, and the enactment of each resulted in a reduction of the death rate. It slid down from thirty-five per 1,000 through 26, 22, 19.6, 16.4, and in 1916 was still lower—15 per 1,000. As Alfred T. White, of Brooklyn, has said, it would not be fair to credit all this reduction of the death rate to the housing laws, but they were certainly a large factor. New York's present population is 5,200,000. The difference between the old death rate of thirty-five and the present of fifteen means a saving of 100,000 lives each year. This is the measurable result of better housing; but the invisible, imponderable result, hundreds of thousands of people who have had better homes and are healthier, happier, and of more value economically, is another and probably more important consequence of the better housing.

One of the worst features of the slum, or near-slum, is the effect upon the young. The children who die there because of the unhealthy conditions at least escape the depravity of those who live. Parents who have had a discouraging struggle with years of unrelieved poverty in the over-crowded quarters of the city, have little time or energy for healthy companionship with their children. Their cheerless, dungeon-like homes are devoid of everything that childhood craves, and

the children are driven to the street or the gilded hall for companionship and amusement. Thousands of boys and girls whose homes are unclean and cheerless find their only playground in the

The above photograph from the files of the California State Board of Health depicts some of the unbelievable conditions which were found in housing survey in the big cities of the state. The beds are placed two-tier deep along the back wall. Light and ventilation were almost totally absent.

street, where many of them are familiarized with vice, and trained in crime. If slums were abolished, the human material that they supply to jails and penitentiaries could be saved to the healthy uses of society. So long as overcrowded and foul homes are permitted, so long will degraded humanity issue from them to prey upon the community.

The child is the future in the making. By the life and the training that it gives the young, society largely determines what this future shall be. People in their mature years usually give to society the kind and quality of service that in their youth it fitted them for. Young humanity is a tender growth and definitely responds to its

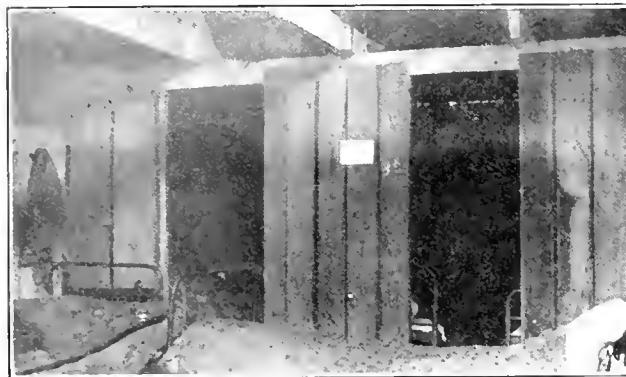

The clothes line on the roof suggests that a home must be nearby. The home is in the foreground, under the California sky. The wagon bed, a dry goods box, and two sheets of roofing iron were the living quarters of the old man in the photograph.

environment. The hundreds of thousands of children in America that daily go out from homes that are below a decent standard will avenge society's neglect in their unfit and incompetent lives. It is not encouraging for the future human quality of the nation that from 60 to 70 per cent

of school children suffer from physical ailments and that 30 per cent of our young men fail to pass the examination for active service in the army. Something is wrong with the homes of a country that produce results of which these are samples.

Economic Phase of the Question

The working capacity and economic value of the individual are reduced by bad conditions of home life. One who lives under insanitary conditions or cheerless home influences cannot do his best work. The interest and animal vigor necessary for good work does not thrive in forbidding surroundings or squalid quarters. The clean and cheerful home adds to the health and physical capacity of its occupants. It does more than this; it has a moralizing and spiritualizing influence that increases the social and industrial value of the individual. Home influences belong to the visible, imponderable things of life. Man carries

Five beds in the space which one bed should occupy.

his home in his mind, and whether he manages a bank or runs a peanut stand, this shelter in which he spends half his life to a large extent determines his health and character.

The Value of the Individual

The well-meaning but incompetent thousands whose lives are tragedies of failure and who pass to the lowest stages of poverty form an ever increasing class. The proportion of the very poor to the whole population is growing. As a consequence the slum is not disappearing; it is spreading. In every city and most villages of the country are the multiplying hovels of the ignorant poor, and it is from such homes that the greater part of disease and crime of the future will come. This does not relate to the healthy poverty that disciplines and stirs to effort, but to the poverty of defeated lives that lessens the resistance and dulls the moral sense. The feeble attempts made to help this class after neglect has allowed the evils to grow, the charities that are only an ambulance service that picks up the injured, these

are chiefly conspicuous for waste of effort and waste of money.

In this age of colossal enterprise and mobilization of workers there is danger that consideration of the individual will disappear in the fury of the industrial struggle. Industry finds it more profitable to deal with men in the mass, as in this way larger results are had and what is called progress is hastened. Armies of men lift great buildings to heights that out-tower the steeples, or they work on railroads or in factories where the first interest of society should be in the human product, healthier men, and better citizens; but interest in the material product overshadows consideration for the individual worker. The important question for society is: How are these workers housed and fed? For the ultimate value of the work lies less in the product than in the workers. Will these people be able to equip their children for good citizenship so that they may add to the social forces of the next generation? The problem of housing concerns itself particularly with this class who do the necessary work of the world and who also contribute a proportionately larger share to the population.

Good Housing in Britain

The garden villages of Europe, and especially those of England, have shown what good housing and a general healthy environment will do to improve the physical condition and the working capacity of laboring people. For more than a generation British cities have been carrying out municipal housing schemes. The earlier work was in the destruction and rebuilding of slum houses. Later, garden villages were associated with manufacturing enterprises and have become really separate and independent communities.

Years ago the authorities of Liverpool began to destroy the buildings in one of the city's worst housed districts. These have been gradually replaced by well-built homes. Up to 1914, the city had spent several millions of dollars on the scheme, and had put back into the new houses the people who had formerly lived in the slum quarters. The district has parks, playgrounds, swimming pools, gymnasiums, and, with better homes, a class of healthy young people is growing up where formerly slum wretchedness and crime were the regular products.

The year before the work of house destruction was begun there were 204 prosecutions for crime in this district. After the new houses were built and the playground and park life had got into the blood of the boys and girls, there were four prosecutions for crime in one year. This is but one item and is a rough, but significant measure.

In the garden villages, in order to give room for sunshine and air, the number of houses is limited to from eight to twelve per acre. In London, Birmingham, and other cities the number of houses is from thirty-five to fifty per acre, with the result of land over crowding. In the garden

Not the kind of hotel that most of people desire, but a hotel nevertheless at least it bore the name of hotel until the health authorities of California insisted on decent accommodations being provided for the guests.

villages, two-thirds of the land is reserved for parks, playgrounds, and swimming pools. The rent is low, and in most of the villages, garden land is furnished where many residents raise vegetables in amount sufficient to pay rent.

The health records furnish evidence of what these villages do for the residents. The general death rate in England and Wales is 14.6 per 1,000; in Bourneville, one of the garden cities, the death rate is 5.7 per 1,000. The infant death rate is 62.4; that of England and Wales is 117.7. At twelve years of age a boy in Bourneville weighs eight pounds more than a boy of the same class in Birmingham, and is more than two inches taller. In Port Sun Light, another garden village, the death rate is eight per 1,000. A boy in this village is, at fourteen years of age, six inches taller, and weighs thirty pounds more than a boy of the same age and class in Liverpool, six miles away.

These results are not obtained by any special methods of feeding or training. These boys are the children of humble people who, living under proper conditions, are able to give their children good food and outdoor life.

The garden villages afford people, old and young, normal surroundings and nothing has been done here that might not be accomplished anywhere else. It is simply a matter of decent housing, producing happiness, health, and efficiency. The lesson of the garden village is that a sanitary and attractive home can be provided for the wage earner at an expense that is within the limits of his income. If a boy in a garden city

at fourteen years of age is five or six inches taller and weighs twenty or thirty pounds more than the boy in the slums, it is only because he has had the food and air and sunlight that all should have. The better opportunities that the poor man has in the garden cities make the difference shown between the life of poverty that is underfed and poorly clothed, and the life of that easily procured and simple abundance that is everyone's right to have.

The poor man is limited in his choice of a home location, as the price of land and the expense of building compel him to make a home not where he would, but where he can. His housing is thus determined for him by economic conditions, and among other disadvantages usually he has to pay one-fourth or more of his income for rent when the right proportion is only one-sixth. If the item for rent is out of proportion to the income, he must reduce expenses in other ways; if this deduction is made, as it would be probable, from food and clothing, having a better house may result in injury. This serves to show how the problem of good housing is more than the house, that it relates to economic conditions, to the wage scale, and to the skill of the workman. If his skill falls below a certain standard, he is in danger of being pushed over into the slum or near it, and despite years of honest effort, and because of overcrowding or other bad conditions that he did not cause and cannot remedy, he and probably his neighbors may become a menace to the health of the community.

A habitation which could scarcely be termed a house.

In cities where slum houses have been destroyed and good houses built to replace them the result has generally been that the previous occupants have established other slum quarters elsewhere. The slum resident is always either underpaid, or inefficient, or both; and if he is to have

that social help and spiritual transformation that lifts him above slum life, he must be cured of the slum disease, and acquire the habit of decent living.

Modern conditions create common interest

Before the removal of a building from the vacant site in the foreground, the dwellings shown in the picture were without back yards, except for narrow courts. Children living in the buildings had their playground in the street.

among people who may never see each other. The age multiplies points of contact; human interspaces grow smaller. A man's health and his housing are not individual affairs, for the community is a social unit and whether one cares to concede it or not he can not afford to be indifferent to the human conditions about him. Diphtheria, tuberculosis, and other contagious diseases are house diseases, and insanitary homes are culture centers from which they spread. A few years ago 93 people in a California town were infected with typhoid fever by a person in good health. Those who live in places where disease breeds touch hands with those who live in the best homes. Any expense necessary to make a community a safe, healthful place to live in is a good investment. It is an investment in human life, in more healthful living, in better citizenship in race conservation, all the more valuable as an investment because it cannot be expressed in dollars and cents.

Physical Basis of Power

The future control of the world will be to the strongest race. As in the past the dominating races have been physically the strongest, so in the future the strongest races will be those that control. Those who are interested in better housing may have a share in making a more vigorous race by helping to give men better homes. At near view the work may seem commonplace, for it deals with homely problems and forbidding conditions. In its deeper meaning it promises a finer

quality of humanity. For this to appear to the home visitor or the worker in the slums requires vision, but without sympathetic insight into the lives of others, such work will never yield the best results. In this and in all other work that has for its object the remaking of the lives of individuals, and ultimately of the race, we need a large patience and a vision that reaches beyond the horizon of the present time.

NATIONAL TUBERCULOSIS ASSOCIATION

The fifteenth annual meeting of the National Tuberculosis Association was held at Atlantic City, June 14 to 17, 1919, with nearly 700 persons in attendance. The program was conducted in four sections, pathological, clinical, sociological, and nursing section. The pathological and clinical sections represented the work of the laboratories and specialists and made a decided contribution to the scientific literature of tuberculosis. The war aspects of the problem and the lessons learned from the war were treated in a number of papers. Discussion of the national health program, the relationship between the tuberculosis movement and the general health campaign and the European experience formed the subject material of the general sessions.

The sociological section discussed the present status of the draft rejects, occupational therapy for tuberculous men, vocational retraining and rehabilitation, and the removal and relief of poverty as factors in the prevention of tuberculosis by the preventive health agencies and by social insurance.

The nursing section dealt with the development of nursing service, the education of public health nurses for tuberculosis work, and the methods of public education to secure support for tuberculosis work.

The address of the president, Dr. David R. Lyman, was devoted to the relationship of the state and national association to the other agencies in the tuberculosis campaign. Dr. Lyman stated that while the war had clearly shown the triumph of modern medicine in the control of acute infectious diseases, it had also shown with equal clearness the great inroads that chronic diseases were making in our national economy. In the attack on tuberculosis, Dr. Lyman regarded as of first importance the cooperation of the national organization with the established health authorities, local, state, and national. He felt this was essential because these authorities had a more comprehensive knowledge of local needs. He called attention to the fact that the national association has for years advocated the creation of a division of tuberculosis in the U. S. Public Health Service.

Mr. John A. Lapp, managing editor of *Modern Medicine*, contended in his address on social insurance that there can be no solution of the problem of tuberculosis among working men and women without health insurance. He suggested health insurance as the independent, self-respecting means as against charity. He believes that a proper plan of health insurance for the tuberculous should provide for payments without limitation as to time and should provide for complete medical and sanatorium treatment as long as the patient requires it.

Bad teeth very often cause rheumatism and joint trouble, according to the United States Public Health Service, which advises that an x-ray examination of the roots be made to learn if they are diseased.

HEALTH PROMOTION WEEK IN CHICAGO

During the spring the city of Chicago held a Health Promotion Week in which school children, teachers, health officers, nurses, and departments of the city government

Ready for action. A team of health promoters who helped clean the back yards, cellars, and alleys in Chicago during Health Week.
(Copyright by International Film Service Co.)

joined hands for a housecleaning. But Chicago's streets and alleys will need another "clean-up" in July on account of the suspension of work during a strike by city employees in the street cleaning and garbage disposal departments.

Commissioner of Health John Dill Robertson, under whose direction Health Promotion Week and the clean-up campaign were held, published the following program for the seven-day crusade against dirt:

Sunday—Health Sunday, cleanliness is health godliness.
Monday—Dental day. The care of your teeth is important. It pays to consult your dentist often.

Tuesday—Cellar and back yard day. Don't be content with putting up a good front—clean up the back yard as well.

Wednesday—Clean up and paint up day. Attractiveness as well as cleanliness counts in adding to the comfort and pleasure of our surroundings. Paint both brightens and cleans.

Thursday—Screens and garbage day. There are many kinds of flies and all are dangerous. Get your screens in now. Keep that garbage can covered at all times.

The illustration shows what happened in hundreds of Chicago back yards during Health week, when the teams got into action. (Copyright by International Film Service Co.)

Friday—Clean milk day. Milk is the baby's food; keep it cool and protect both against the nasty, dangerous fly.

Saturday—Clean food day. Conserve both your dollars and your health by trading at the clean food store.

NATIONAL CONFERENCE OF SOCIAL WORK

The National Conference of Social Work, held in Atlantic City June 1-8, was replete with interest to the workers in the health and hospital field. The subject of better health and the means of attaining it were discussed in a broad, constructive way not only in the "permanent" section on health, but also in several other sections, notably those on mental hygiene and children. Moreover, Miss Julia C. Lathrop, chief of the Children's Bureau, U. S. Department of Labor, in her inspiring presidential address on "Child Welfare Standards—a Test of Democracy," stressed the necessity for the provision of adequate care for the health and welfare of all mothers and children as an integral part of the general welfare.

The division on health, with Prof. C.-E. A. Winslow as its chairman and with a well-developed program, conducted a series of informing and stimulating meetings. The standard of living was discussed in relation to tuberculosis, medical and nursing care, infant mortality, venereal disease, family food supply, housing and the health hazards of industry. Mr. Karl de Schweinitz, secretary of the Philadelphia Society for Organized Charity, in his paper on "Sickness as a Factor in Poverty," brought out some startling figures as to the importance of the sickness factor in terms of days and money lost in the course of a single year by the people of this country. Dr. Royal Meeker's paper on "What is the American Standard of Living?" combined wit and humor with valuable statistical data. He declared there was no single standard of living, but many standards, as was abundantly attested by the statistics gathered by the Bureau of Labor Statistics, of which he is the head. Dr. Edward T. Devine spoke on "The Outlook for the Future."

The new officers of the conference are: President, Owen R. Lovejoy; vice-president, Gertrude Vaile, Denver; Rev. John A. Ryan, Washington; Robert W. Kelso, Boston; with William T. Cross continuing as secretary. Mr. George T. Nelbach, secretary of the committee on tuberculosis of the New York State Charities Aid Association, was elected chairman of the health section, and Dr. C. Macie Campbell, Baltimore, of the section on medical hygiene.

The program included speakers and subjects, as follows: Dr. Charles J. Hatfield, managing director, National Tuberculosis Association, "The Economic Factors in Tuberculosis"; Bailey B. Burritt, general director, Association for Improving the Condition of the Poor, "Raising the Standard of Living as a Weapon in the Antituberculosis Campaign"; Dr. Lee K. Frankel, third vice-president, Metropolitan Life Insurance Company, "How Far Does the American Family Budget Provide for Necessary Medical and Nursing Care?"; John A. Lapp, managing editor of MODERN MEDICINE, "Health Insurance as a Means of Securing Medical and Nursing Care"; Dr. C. C. Pierce, assistant Surgeon General, Public Health Service, "Federal Campaign Against Venereal Disease"; Dr. Thomas Adams, town-planning adviser to the Commission of Conservation, Ottawa, Canada, "Housing Development as an After-War Problem"; Dr. Irving Fisher, Yale University, a plea for humanizing industry; Dr. René Sand, professor of social and industrial medicine in the University of Brussels, "Minimum Standards of Child Welfare."

SICKNESS COSTS AND THE FAMILY BUDGET

By LEE K. FRANKEL, THIRD VICE-PRESIDENT METROPOLITAN LIFE INSURANCE COMPANY, NEW YORK CITY*

ATTEMPTS to study family expenditures to determine the amounts necessary for various items in the budget have been made at frequent intervals for over two hundred years. As early as 1672, William Petty made an estimate of the cost of living of labor in England and Ireland. Similar studies were made by Vanderlint in 1735, by Massie in 1756, by Cantillon about 1750, and by Edward Atkinson, who presented to the Aldrich Committee in England in 1892 an estimate of the expenditures of a laborer's family with an income of \$500.

All of these studies as well as later ones are mentioned by Chapin in his "Standards of Living in New York City" and need not be discussed further at this time. Chapin's book was an elaboration of the report of the Committee on Standards of Living appointed by the New York State Conference of Charities and Corrections with the writer as chairman.

Home Finances a Complex Problem

I remember well the difficulties which were encountered in making this investigation. The investigators who were sent into the homes had to receive the most careful instruction in order to qualify them for their task. Even with this, much difficulty was experienced in educating families properly to carry out the instructions which were given to them. The schedule which was used by investigators was quite an elaborate one. The experience which I have had with much more simplified schedules leads me to believe that the average workingman's family finds it exceedingly difficult to keep an accurate account of its daily expenditures and to enter them properly in the schedule. An experiment was made quite recently in a girls' high school in New York City to ascertain how well girls of this grade were competent to fill out a quite elementary schedule. Out of more than fifty schedules submitted to the teacher, practically none was correct in the final addi-

The Metropolitan Life Insurance Company has sought to determine what amount should be provided in the family budget for necessary medical and nursing service.

That insufficient allowance is made, or none at all, by many families is shown by the fact that in every income group, the sums paid to physicians are paid by a few of the number. The doctor never enters the homes of many families, whose budget makes no allowance for sickness costs or medical attendance.

The expenditure for medical service in several income groups, up to \$2,500 averages from 3 to 5 per cent.

tion. The data given by Chapin are, however, not applicable to present day conditions. The cost of living has changed so considerably since the Chapin studies that they are of comparatively little merit to-day. Certain recent studies are, therefore, much more to the point as an indication of the extent to which the average family budget provides for necessary medical and nursing care. It is assumed that under medical care is included services of dentists, oculists, and opticians.

4 Per Cent of Income, the Average

The Industrial Welfare Commission of California published in the year 1917 the records of one year's expenditures of 600 working women in San Francisco and Los Angeles. The records were classified according to their earning capacity and occupation. The amount spent by each group for medical services was approximately 4 per cent of the income. It should be noted that about half of the total amount expended for physicians and medicine was paid out by twenty-one of the entire number. Three hundred and one, or more than 50 per cent, apparently had no expense for service of this kind.

Similarly, in a group of 251 laundresses, the expenditure for medical and dental care amounted to 5.1 per cent of their aggregate earnings. The bulk of the cases in this group had an actual income of from \$350 to \$500 per annum. The average annual expenditure for medical and dental care was approximately from \$18 to \$25 per annum.

The Commission also presented the records of 264 waitresses. In this group, 3.9 per cent of the aggregate earnings was expended on medical and dental bills. These women belonged to a waitresses' union, which employed a physician to care for them. Apparently service was obtainable at a lower cost under this contract plan. Whether the service was equally good, however, is not stated. The larger number of women in this

*A paper read before the Health Section of the National Conference of Social Work, Atlantic City, N. J., June 5, 1919.

group were earning between \$500 and \$600 per annum. The average amount spent for medical and dental care was approximately \$20 to \$25 per year.

The United States Bureau of Labor Statistics has recently made studies of the expenditures for medical and dental care by workmen in certain industries. The data has not yet been published. It is due to the kindness of Dr. Royal Meeker, Commissioner of Labor Statistics, that certain of the figures are given here. One of the studies for the year ending March 31, 1918, made among 508 families in Cleveland, Lorain, and Toledo showed an average expenditure of \$41.79 for medical care and \$8.59 for dental care. Twenty per cent of the families in this group spent less than \$10 for medical care and more than 17 per cent between \$10 and \$19. At least two-thirds of the entire group spent less than \$40 per year for medical care. In Columbus, Ohio, a similar study of 211 families showed that \$42.41 was spent for medical care per family and \$6 for services of the dentist. Nearly 20 per cent less than \$10 per annum, and nearly two-thirds were in the group under \$40. The Columbus figures are thus in close agreement with those for Cleveland, Lorain, and Toledo.

Families Make Use of Clinics

A similar study under the auspices of the United States Bureau of Labor Statistics was made in the District of Columbia. Here the average expenditure for medical care during the year 1916 was \$37.75. For 230 colored families, the amount was \$20.19, while for 692 white families, the amount was \$43.59. These averages are in fairly close agreement with the data obtained in the Ohio studies. The Washington studies, based on income, gave data corresponding to those obtained in the studies made by the New York Committee on Standards of Living as will be seen from the table below. These figures are for the white families:

INCOME	EXPENDITURE
Under \$600	\$12.83
600 to \$ 900	25.52
900 to 1,200	42.31
1,200 to 1,500	43.16
Over 1,500	59.57

It is quite probable that in Washington, as in New York, families of lower income utilized the agencies in the city such as hospitals and dispensaries, where service was given either free or at a nominal cost.

Another study made by the Bureau of 301 families in Philadelphia, containing on the average five persons per family, showed an average expenditure for medical care of \$57.92. This is a little more than 4 per cent of the average annual

income. These figures, like the Washington figures, show increased expenditure along with increased income. The data submitted shows an average expenditure ranging from \$24.13 for the group with an income under \$900 to an expenditure of \$141.57 for the group over \$2,500.

Medical Care Costs \$23.18 in \$900 Group

In Boston the Bureau studied 407 families. These, too, averaged a little more than five persons per family. The average expenditure for sickness was \$49.76, or about 3½ per cent of the average annual income. Here, again, the expenditure varied with income. In the group under \$900 there was an average outlay of \$23.18. In the group over \$2,500 the average expenditure was \$67.42.

In a group of seventeen Pittsburgh and thirty New York families studied by the Bureau, whose income ranged between \$1,100 and \$1,399, the average amount expended for sickness was \$42.70. In a similar group of fourteen Pittsburgh and twenty New York families, with incomes ranging from \$1,400 to \$1,699, the average for sickness was \$38.60. In a group of sixty-two families in ten representative cities of the United States, with incomes varying from \$1,700 to \$2,100, the average amount expended was \$73.28. In a group of eighteen families in eleven representative cities, with incomes ranging from \$2,100 to \$3,100, the average expenditure was \$57.04.

It will be seen from the data submitted how difficult it is to determine to what extent the American family budget provides for necessary medical and nursing care. None of the studies convincingly prove at what point in the income the family finds itself compelled to make use of gratuitous medical service. In fact, it is well known that even among the poorest there are those who, in an emergency, will use their last penny and, if necessary, borrow from friends and acquaintances to obtain the highly prized services of medical specialists. For these reasons the data given are indicative only. It may be fair to assume, however, from the more recent investigations, that the average expenditure of a family in the \$1,000 income group may vary from 3 per cent to 5 per cent of the total income.

Comparatively few of the budgetary studies thus far made give sufficient data on the cost of dental, optical, and nursing care. This is not the fault of the investigation. It is due to the fact that service of this kind, for the large masses of people, is still in its infancy. The education of the people in oral hygiene is a matter of very recent growth. The same is true of the care of the eyes. Nursing service in the home for the self-sustaining and self-respecting workman is ex-

ceedingly limited. The services of the private duty nurse cannot be considered by the average workingman's family owing to the cost. Visiting nurse service, until very recently, has been primarily for the poor. Notwithstanding the fact that within the last decade hundreds of visiting nurse associations have come into existence in the United States, the great majority are still on a semi-philanthropic basis. One of the greatest needs of the day is an adequate bedside service through visiting nurses for workmen who do not wish to receive charity.

Families Without Nursing Service

As an indication of the cost of such service, the experience of the Metropolitan Life Insurance Company is probably most indicative. In the year 1918, the company nursed 290,882 policy-holders, making 1,431,085 visits. The average cost per case with a physician in attendance was a trifle over \$4. Since the cost per visit was 51 cents, the average patient received approximately seven or eight visits. The Bureau of Labor Statistics in its Columbus, Ohio, studies showed that out of the 211 families investigated 174 families had no disbursement for nursing service. This does not mean that these families did not require such service. Six of the families spent less than \$10 per annum; fourteen families spent between \$10 and \$19 per annum; six between \$20 and \$30 per annum, and the other eleven families spent amounts varying between \$30 and \$80 per annum. In the studies made in Philadelphia and Boston, the average amount spent for nursing service in all income groups was \$2.50. In Philadelphia this figure was fairly constant in all income groups up to \$2,500, where the average was \$5 per annum. In thirteen families in Boston, with an income of over \$2,500 per annum, no family had any expenditure for nursing service.

Average Sickness of Individuals

Probably some light may be thrown upon the subject if we study it from a different angle. In recent sickness surveys made by the Metropolitan Life Insurance Company, it was shown that the average individual is sick seven days per annum. These surveys included, however, only individuals who were sufficiently ill to be unable to work. It can be assumed that all of these individuals should have been under medical care. The surveys showed quite clearly, however, that in a number of communities a considerable proportion of those disabled by illness were receiving no medical attention whatever.

If we take as our unit the average family of five, consisting of father and mother and three children, and use the above average of seven days'

illness per member, we may assume that in such an average family there are thirty-five days of illness per annum. On the assumption that half of the incapacitated are chronic invalids who do not require the daily visit of the physician, it is probably not an exaggeration to assume that the thirty-five days of illness would require seventeen visits. The cost of a physician's visit in the home has increased along with the other necessities of life. It is doubtful whether in the large cities physicians' services can be obtained today under \$2 per visit. This would mean \$35 per annum for physicians' services alone. It is true, of course, that many of these patients are in hospitals and institutions. The cost of this hospital service would probably run as high as the cost of the physicians' visit to the home. It is quite unlikely that the average modern hospital can give service under \$2 per diem. It is immaterial, of course, whether such service is given free or is paid for. It must be included in the amount which should be provided in the family budget for self-sustaining families. Some of the incapacitated who are able to be up and about will make use of dispensary service. According to the figures of Mount Sinai Hospital in New York, the consultation visit in 1918 cost the institution \$0.45. The average patient makes from three to four visits. In the Massachusetts General Hospital, the cost per consultation is approximately \$0.50.

Extra Expense for Dental Care

In this calculation no provision has been made for dental care of the members of the family. In the opinion of competent oral hygienists, prophylactic care should be given to the teeth at least twice a year. Assuming that it were done only yearly, the expense for this would be at the lowest possible estimate approximately \$10 per annum. Nursing care given by a visiting nurse would vary from \$10 to \$20 per annum. It is difficult to make any estimate of the cost of eye-glasses and the care of the eyes generally but it would be safe to assume an expenditure of \$10 per annum.

I recognize quite fully that these are mere estimates and that they may fall very wide of the mark. On the other hand, these estimates combined with the investigations previously made, indicate quite clearly that an allowance of \$50 per annum should be made in the average American family's budget for medical, nursing and surgical care. It should be remembered, of course, that these are averages. Some families may go through the year with practically no expenditure; other families, on the other hand, may in an unfortunate year have an expenditure running into hundreds of dollars. Covering a period of years, however, it is fairly certain that the average family would

average a minimum of \$50 a year. It would not be difficult to increase this average to \$60 and even to \$75 per annum.

From what has been said, I think it will be realized that at the present moment we have not

sufficient data for a definite statement of the amount which should be provided in the family budget for necessary medical and nursing care. It would be highly desirable to have an exhaustive study made to determine the facts.

FREE DENTAL CLINICS FOR RURAL SCHOOL CHILDREN IN NORTH CAROLINA

BY GEORGE M. COOPER, M.D., DIRECTOR, DEPARTMENT OF MEDICAL INSPECTION OF SCHOOLS, RALEIGH, N. C.

LESS than one hundred years ago the science and practice of medicine was regarded by the average man as more or less on a par with the training of the barber. Only a few short years ago in almost any crowd someone was ready to express the opinion that the dentist and the dental profession were about on a par with the blacksmith. Happily all such ideas together with the causes which prompted them are passing away.

A little more than thirty years ago the empire of Japan made compulsory the medical inspection of school children by competent authorities. In 1907, after the Boer War in South Africa, the British Government passed a compulsory medical inspection act for the British Empire. In both cases this was not done until thinking people of the two countries had been aroused to the necessity for the physical education of the people, and the care of their health had been recognized just as necessary as their mental development, and that, indeed, the safety of the Empire depended upon the physical stamina of the people.

In America medical inspection of school children has been somewhat a patchwork affair. Here and there, in some cities over the country, a worth-while system has been developed. Few of the states, however, have enacted state-wide laws on this subject.

In North Carolina the General Assembly of 1917 enacted a law requiring the teachers to do a preliminary physical examination for each child

in the schools of the state once every three years, their findings to be recorded on the card prepared by the State Board of Health and approved by the Department of Education, all executive responsibility for the performance of the work being left in the hands of the State Board of Health. For some three years previous to that time, the State Board of Health had supervised the inspection of many thousands of school children. Through their press service many facts were given to the people concerning the physical condition of the children in the schools of the state. What in the opinion of many is regarded as the most forward step of any state in the Union on this subject was taken when the legislature of

Dentist at work in the permanent Dental Dispensary at the Court House in Rowan County, N. C., where free dental service is provided for all the school children of the county.

1919, assembled in January, greatly broadened and strengthened the law governing the physical inspection of school children and appropriated a

fund of \$50,000 per year from the public school funds to be used by the State Board of Health in the examination and for the dental treatment of school children.

Provide Records But No Remedy

Practically everywhere in the United States, with the exception of some of the more progressive cities, the medical inspection of school children consists in the examination and the card indexing of the children, that is, the defectives, with the simple notification to his parent to have the defect remedied. Some take the advice, many are indifferent, and a large percentage are unable to have anything done. In the experience of the writer as a county health officer, as a medical inspector, and as an official of the State Board of Health in the thousands of examinations which had been made for school children in this state in the routine manner, the great need that something more definite and specific be done for these multitudes of children remains constantly in mind.

Therefore, when the law of 1917 was put on the statute books and the director of this bureau was charged with the responsibility of executing the law and of really doing something for the defective children, plans based on the experience of many years were immediately formulated for a systematic remedying of the conditions found. It was natural to begin on the most outstanding defect; so, when it was known that not less than 80 per cent of all the school children in the state needed dental treatment, and considered of paramount importance to the child's future health and happiness that proper care for the teeth be given in time, it was easy to decide what to do. The first point to be settled was, of course, obtaining the funds and deciding whether to make the clinics free or to attempt a self-sustaining plan. Being strongly of the opinion that treatment for any physical defect should be as free to a school child as the public school itself, this point was

easy to settle. Therefore, later, when the clinics were open, the service was made free to every school child between the ages of six and twelve years whose teacher had made the proper preliminary examination and reported as required by law. No distinction as to race, sex, color, class, or financial standing was made. The funds were obtained by appropriating public money, and thus

The children in attendance at the dental clinic shown in this photo came from a distance, some of them as far as twelve miles, reporting at 8 o'clock in the morning and keeping to the minute an engagement made for them six weeks previously. The photograph shows the permanent dental infirmary at Winston-Salem, N. C., for the free treatment of school children of Forsyth County under the age of twelve years. Those in attendance include the county health officer and the matron who brought the children. For the three months ending April 30, 1919, there were 939 children who received free treatment in this clinic.

it was made a business proposition and removed entirely from the realm of charity.

One of the next problems to consider was what would be the attitude of the dental profession of the state toward such a radical departure from precedent. This position was freely and frankly discussed with the dental society of the state, and be it said to their credit that to a man they have loyally supported the work. They were far-seeing enough to know that it not only meant salvation to the health of thousands of children, but that it meant the ennobling and elevation of the entire dental profession, which has already taken place in marked degree.

As previously stated, with the exception of the progressive city work like that of the Oral Hygienists of New York City, the Forsyth Institution in Boston, Bridgeport, Conn., Rochester, N. Y., and Detroit, Mich., no precedent for any of this kind of work was found, nothing whatever pertaining to the solution of the rural problem. The only thing was some experiments made by the Red Cross on a very small scale in one county

in Michigan, and by the Vermont State Board of Health, supported by private donations. The latter two plans were radically wrong in that the Red Cross activities made an effort, according to their report, to single out the children of the

The first day's work of a free dental clinic for school children at one of the rural schools in Lenoir County, N. C.

poorest, while the Vermont work was done by private donation. This is a public responsibility, and should be provided by the tax payers just as is the teaching of arithmetic and spelling.

Organization and Results

To make a long story short, when we began definitely arranging our plans for and inaugurating this work in the early spring of 1918, we found that we were embarking on an uncharted sea. However, the results have a thousand times more than justified the adventure. This kind of work has come to North Carolina to stay. For the benefit of those interested in the details of our methods, the following summary is submitted:

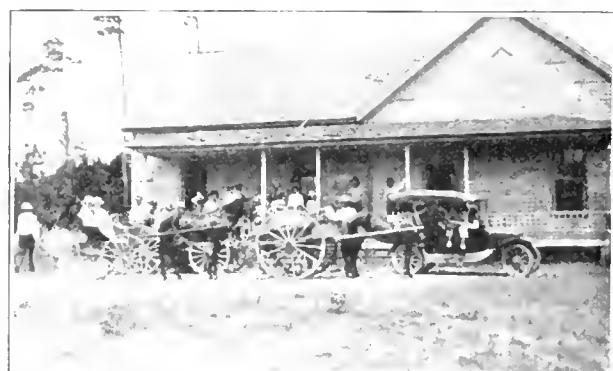

Six dentists who had been recently graduated and licensed to practice in the state, all young

was planned. Each man was supplied with a McConnell folding chair, a foot engine, a student's cabinet, a few simple drugs like novocain, tincture of iodin, oil of cloves, and a full equipment of instruments, such as excavators, elevators, burrs, brushes with pumice, with dental alloys, and the necessary material for the simpler fillings. Each one was placed in an automobile and taken from place to place over the county, and the children were summoned by local agencies. The work was done for children between the ages of six and twelve years only. No synthetic or gold fillings were undertaken, no crown or bridge work done; diseased pulps received only temporary treatment, and root canals were not treated. The work consisted mainly in the placing of amalgam fillings for the six-year molars, and other permanent back teeth, some temporary fillings, silver nitrate treatment, etc., cleaning and extracting when necessary. The educational and prophylactic side of the question was stressed at all times as the most important. The work, ending early in December, resulted in the treatment of nearly seven thousand children in the nine counties. More than 227 dispensaries were held, and over one hundred lectures on oral hygiene made.

Three dentists have been employed nearly all the time since the first of January. Beginning with August 1, this force will be increased to nine, but, as we always prefer to talk about something after it has been done, the result of this year's work will suffice for another story. Naturally in a state with 800,000 school children, more than three-fourths of them needing dental treatment, it is unthinkable that a very large percentage could be reached by nine dentists working all the time, but when the propaganda is spread all over the state and the people have preached in these and other homes in every section knowledge concerning the importance of the care of the teeth, and the fact that the state is sufficiently interested to put up thousands of dollars a year in the effort to supply this care, he is a pessimist indeed who cannot see that the result of the work will have an enormous influence upon the health of the children of this and the succeeding generations.

Creates County Health Committee

The Coe law in Wisconsin makes it mandatory for each county in the state, within two years from July 1, 1919, to employ one or more registered nurses for public health service as supervisors and instructors, who will work under the direction of a Health Committee to be composed of the chairman of the County Board, the county superintendent of schools, a woman member to be appointed by the County Board, the judge of the juvenile court, and the deputy state health officer of that county.

Moss Hill School in Lenoir County, N. C., in which thirty-three children from twenty-three households were given free dental treatment in the Traveling Dental Service conducted in that county by the North Carolina State Board of Health. The illustration shows how families rode to the clinics.

men of high type, were selected to do the work. A plan of campaign running from four weeks to three months in each of nine counties of the state

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., Editor

THE REHABILITATION OF INDUSTRIAL CRIPPLES

A BILL has been introduced into both houses of Congress by Senator Smith, of Georgia, and Representative Fess, of Ohio, providing for national assistance and guidance in the development of vocational rehabilitation of industrial cripples by the states. The bill ought to be perfected and passed without delay in order that the experience in rehabilitation of soldiers and sailors may be fully utilized in this larger problem.

Dr. Frank Billings in a notable paper in the *Journal of the American Medical Association* states: "The application of mental and physical rehabilitation to sick and disabled soldiers by practically all of the nations engaged in the war has proved so successful and beneficial that it imperatively demands application of like measures for the benefit of the disabled of the army of the industrial world."

Two years ago this problem was scarcely thought of. Today it is receiving the serious consideration of medical men, educators, and statesmen. There are some considerations, however, which should be taken into account in making the final draft of the pending bill.

In the first place, the act provides only for vocational rehabilitation without making any requirements for physical rehabilitation even in the case of persons disabled in industry. It must be apparent to everyone that medicine must do its part before vocational education will properly function with the disabled. Much waste would occur if vocational education is not preceded by physical restoration so far as medicine can bring it about.

In the case of persons injured in the course of employment the physical restoration of men should be brought about under the terms of the

workmen's compensation acts. It is the part of the burden which should be borne by industry, and it ought to be required as a part of the workmen's compensation acts before Federal aid would be given for vocational reeducation.

Fortunately the stupid mistake made in the bill introduced a year ago has not been repeated in the present bill, namely, that rehabilitation should be confined to persons injured in the course of employment. The muddled thinking which conceived the idea of providing at public expense rehabilitation for persons injured in industry only, a burden which in justice ought to be thrown entirely upon industry, is hard to conceive.

It is necessary to coordinate the workmen's compensation administration with the educational authorities in a more concrete way than the bill now provides.

The sound principle of grants in aid which has been so successful in the fiscal administration of Great Britain and also in a number of the states, has been adopted by our Federal Government in the aid given for vocational education. The new bill wisely extends that principle to cover the reeducation of cripples. Under the plan the initiative and organization of the scheme are entirely in the hands of the state and local authorities, but they must meet and live up to certain minimum standards set by the Federal Government if they are to receive the support of Federal funds.

The plan constitutes a partnership between the Nation and the states to achieve a great national purpose in which the Nation agrees as a nonresident partner to contribute money, provided the states set up ample machinery to make the gift effective. It is regretted that the bill provides merely for a nominal appropriation. The project is large and it will not be long before several million dollars will be required as the Federal portion of the enterprise.

WHAT THE SOCIAL WORKER LEARNS FROM THE PSYCHIATRIST ABOUT HER PROBLEM CHILDREN

BY JESSIE TAFT, PH.D., DIRECTOR DEPARTMENT OF CHILD STUDY OF SEYBERT INSTITUTION, PHILADELPHIA

THE social worker, particularly the children's worker, is looking for a new psychology. The psychology she studied in college is somehow unwilling to detach itself from the book. It remains where she found it on the printed page, unrelated to life. What the social worker seeks is a psychology that works; a psychology that she can use to make people over. The youngsters who fill the Juvenile Court, the Children's Aid Society, the truant school, the Society for the Prevention of Cruelty to Children, even the schools, continually present immediate and practical problems in conduct, the solution of which depends upon a psychology that can alter behavior.

At first sight the psychologist with the mental test seemed to promise salvation. And he did help tremendously. He eliminated for the children's worker the hopeless material on which her time would have been wasted and he indicated the presence of intelligence and special abilities or disabilities which gave the basis for constructive work.

After this was done there still remained the problem of an intelligent Johnny who persisted in lying and stealing, or a bright Mary who refused to make progress in school. Anomalies of behavior in children whose intellectual ability is at least average constitute the crucial problem for the children's worker to-day in every field, in child-placing and education no less than in the field of delinquency.

There are those of us who believe that the new psychiatry holds the key to this all-important situation, that what the children's worker needs the psychiatrist has, not an abnormal psychology, although it has been evolved in the treatment of the mentally ill, but a pragmatic psychology founded on human behavior. The psychiatrist's psychology from the start has been subjected to the acid test of direct results, always his theories

PUZZLES OF CHILD BEHAVIOR

Wrong conduct and harmful reactions in behavior among children intelligent and normal in other respects constitute the crucial problem in children's work to-day. What the children's worker must have is a psychology that will change behavior. Academic psychology has failed. Yet the child mind is plastic and will permit of adjustment as well as maladjustment.

The psychiatrist offers a dynamic psychology, a normal psychology evolved in the treatment of abnormal conditions, a psychology that helps to solve behavior problems.

We have to rid ourselves of our undue reverence for reason and intellect and our contempt for or shamefaced concealment of all that goes with instinct, feeling, and emotion. Biology tells us that reason and intellect are very fine but recently acquired instruments for adapting organisms to environment. The core of life is that which moves, the will to live, impulse, that which desires and wants and strives, without which nothing has value, not even intellect. Yet the reason and the intellect are the usual avenues of approach to altering behavior. No wonder we have failed. At least, if we succeeded it was because we used other methods unconsciously. It is when impulse and emotion become blocked, distorted and twisted that human beings get into trouble and it is only by unblocking, untwisting and finding satisfactory outlet for these same impulses and emotions that behavior is changed. Before we can do this, however, we have to understand what life energy, or whatever you choose to call the moving force in human life, is trying to achieve by aid of intellect and reason. Biology sees life as a long history of energy seeking to persist in individual forms and in reproduction of new individuals by developing more and more successful and more delicate machinery for overcoming obstacles and attaining its ends. The evolution from the one-celled animal who meets all of life's requirements by flowing around food substances and away from poisonous particles, to the nervous system of the human being with its

are checked up by the recovery, improvement, or nonrecovery of the patient. What he has discovered about the moving forces in human nature is intended for use and ought to give us the cue for re-educating our maladjusted children.

Those of us who have grown up in a Puritan or New England atmosphere have much to learn before we can make use of the psychology of the psychiatrist.

infinite possibilities of discrimination and subtlety, is a long journey, but the end and aim of the process have not altered. The ameba and the human being can both be explained in terms of adaptation or adjustment. Intellect, self-consciousness appeared not to supersede impulse but to create new and better avenues for its expression in a world made up of hard and resisting reality. It is as if there were a never-ending game between something we call energy and something we call reality, and the object of it all is that energy shall somehow satisfy all the conditions imposed on it by reality and still fulfill itself, still keep moving onward, creating new ways of life for itself. This, you say, sounds metaphysical and speculative but that does not matter if it gives us something we can use in a practical situation; if it works.

Social Adjustments and Conduct

With just this much of introductory theory we have two instruments for going at a human problem. *First:* We can see when we have a child who is stealing or lying or running away or staying too much by himself or flying into fits of temper, that this conduct is, after all, an adjustment, however inadequate, and that it is not primarily conscious or rational. It is all the child has been able to do with forces and circumstances in his life. It is his way of re-acting to something that is real for him, his method of satisfying an imperative instinctive need. Putting a label on this conduct, calling it by any name, learned or otherwise, having a personal feeling, reaction against it, as disgust, horror, indignation, discouragement, arguing or moralizing with the child, all of these ways of approaching this particular behavior are beside the mark. We must understand what the child is adjusting to by this form of behavior before we can do anything constructive. Finding out what purpose a given form of behavior is serving in the life of a child, who is not conscious of the basis of its actions, is a most difficult and delicate task, requiring intimate knowledge of the child, his history and environment, but we have made a start when we have learned to look at conduct, however strange or reprehensible, as an adjustment, no different in kind from highly social and approved ways of behaving. *Second:* from just this much of background, we can look at our problem child and say to ourselves, "this manifestation that so annoys and troubles me is an expression of energy, life force, and as such it is absolutely valuable. I can't destroy it without destroying the child. It has a right to expression and it will be expressed somehow as long as the child continues to live. Unless I can find some other way for this energy to come out, that is social and beneficial and still actually satisfies the

instinctive need that the present behavior is fulfilling, I shall fail with this child. If I stop up this outlet, another worse one may be found which I may not even know about, so that I shall not be able to tell what is happening: that is, I lose all hope of control if I do not know where the energy is going and have no way to get at it. My work begins, not with stopping up present channels, but with finding new ones. And with it all, I need to remember that what would be an outlet for my energy may not be one for the child. I can not afford to be offended if he does not take to the new channel I choose. It is his need, not mine, that sets the conditions of the experiment."

From this general attitude toward the child who constitutes a problem, let us go on to a more concrete idea of the kind of adjustments that any person has to make in growing up, because it is in the failure to make successful adjustments to reality that we find the roots of delinquency and functional mental disease. Let us try to get a schematic picture of the life history of any individual as the psychiatrist finds him so that we may see in general what the possibilities of failure are.

The Habit Basis of Conduct

The baby is born with an impulse to live, to push on, to try to satisfy his wants. But that is not the whole story. If energy just went ahead directly, with unimpeded force, having only external obstacles to meet, life would be comparatively simple. The thing the baby has to reckon with from the first is a tendency *not* to go ahead, a weight or drag on activity, a kind of instinctive laziness or inertia, that is only to be overcome by the necessity for going ahead in order to preserve life. The psychiatrist calls this the safety motive, because it represents that instinct for *not* taking risks, for staying in one spot rather than chancing the danger of moving, for clinging to the old, and established, and familiar, even when not satisfactory, rather than running into the possible danger of a new experience. It is this backward pull of life that makes human beings shun what is hard, avoid effort, and when carried far enough, choose death in preference to life.

The psychologist calls this the habit basis of conduct. Now, habit is certainly not bad in itself; it is absolutely essential to progress that there should be a firm established basis from which to go forward, something settled and not demanding attention. It is only when habit comes to be the end and aim of existence, when the life energy, instead of going on to break new paths, sinks back into a safe, comfortable bed of familiar routine, that it becomes a source of danger and disease. The forward pull, the energy which face new facts

and works out ways of meeting new situations that threaten the life of the organism, the psychiatrist calls the reality motive. He might have called it the creative push, or the constructive motive. Life in any human being consists of the never-ending struggle between these two tendencies, both of which are part of him and both of which are essential. If he is to preserve life he must play safe, and be ready to check any action that seems to involve risk; on the other hand, if he is to remain safe, he must take risks, he must go forward; if he stops moving he dies.

Perils of Unguided Energy

In the balance of power between these two motives, we find all possible degrees of good or bad adjustment. The ideal is to have just enough pull-back, just enough weight of habit and custom to stabilize without checking the on-going energy. The most perfect failure, short of death, is to have the safety motive so strong that no attempt is made to meet the issues of life, and connection between the mind and reality is practically severed. Desire and impulse still remain but they are satisfied without effort in a world of dreams. This condition has a name with which we are all familiar, dementia praecox. In the opposite extreme of unbalance, we find energy so free, so uncontrolled, that it tends to be utterly dissipated in every direction, there being no resistance, no background of solid known habit to give its activities meaning or relation. In this case energy does not evade reality by sinking back away from it but by trying to cover all of reality at once, as it were. This is not quite so serious a mental state as the first, because there is still a recognition of reality and a going out toward it, however ineffective. This state of mind is characterized by the term manic.

In the children we work with we find every kind of possible combination of these two motives, and in each child this eternal conflict is forever raging. Why one child should feel the pull away from people and things so strongly, why he should find it such an effort to meet the everyday, practical problems of life, and another should be so stimulated by every object he sees that he can select no single one for prolonged attention, no one knows. Heredity and constitutional bias account for part of it, in some cases are apparently entirely responsible; but there are so many influences in environment, in the make-up of parents, in various physical handicaps, which we do not yet understand, that when we are dealing with children we ought to be slow to fall back on the notion of hereditary taint or inevitable tendency toward mental disease. Our problem

with the child who tends to avoid practical issues or social contacts is to find some way of giving a stronger push or pull to the reality motive, some way of putting more interesting, exciting stimuli into the environment and of persistently encouraging the child to respond to them. In the case of the other type of child who never sticks to anything and responds to everything, we have, it seems to me a more discouraging and difficult task, but it is essential that we try to find a way of eliminating disturbing and distracting factors, reducing stimuli, and with endless patience and steadiness, help the child maintain interest in a single action or in related activities for longer and longer periods of time.

One should remember that only the extremes of this conflict mean mental disease. It is a normal, necessary conflict, present in all of us in varying degrees. We all waste energy in the face of a task demanding unusual effort by sheer, pull-back resistance, or we waste it and evade the hard job at the same time by finding a multitude of distracting things to do. The fact remains that undue waste of energy in either direction means bad adjustment, and, when noticeable in children, is worthy of every effort at modification or correction.

The Stages of Mental Growth

In one sense, we all have a bad start in life. We begin existence in the uterus in a state of perfect dependence which is at the same time perfect independence. Every need is supplied with no effort on our part. After our entrance into a world which is not there for the sake of supplying our wants, but from which we have to obtain our desires by persistent intelligent effort the course of normal development is a gradual but steady growing away from the self-contained satisfaction of foetal life, through the dependence of childhood, with its family protection, to an independence based on the ability of the individual to face reality squarely on his own two feet and obtain his satisfactions legitimately by working for them, that is by meeting reality on its own ground and forcing it to satisfy his needs. In other words, normal adulthood is an achievement. We attain it in face of that foetal ideal of an effortless state of utter peace and satisfaction. We attain it in spite of the fact that every stage on the way seems an easier, more comfortable kind of existence than the one ahead which spells growing energy and effort. We attain it not only despite external obstacles but despite the internal warfare of our own conflicting impulses.

As a matter of fact, however, many of us do not attain it. We stop at all the possible stages of semi-dependence on the way, but physically and

temporally we appear to be grown up. We live in an adult world which expects us to respond to adult problems on an adult basis, yet some of us have only infantile, childish, or adolescent ways of meeting life. We have no adequate response to adult demands. We are the people who have all kinds of more or less mild mental disorders, called psychoneuroses, neuroses, hysteria, and so forth. We do not pull back so hard or go forward so fast that we lose our grip on reality but we fail to meet life on an intellectual level. We are unable to organize our own warring impulses. We dodge and evade and take refuge in childish reactions. We cling and depend and comfort ourselves with all kinds of self-deception. We are not able to face hard, disagreeable facts, or make them less hard and disagreeable by our own efforts, so we have to be more or less blinded to life as it is, in order to endure it at all.

Evolution of Ideals

For the sake of clearness and simplification, let us reduce impulsive life to two general trends or tendencies out of which all the complicated interests and desires of the adult develop. One of these main trends of impulse is that push ahead which aims particularly at maintaining and furthering the life of the individual, self-preservation, expressing itself chiefly in activities to protect life by offensive or defensive measures and to obtain food. This tendency develops into all the complicated forms of work and play and creative activity. Its beginning is the ideal of nutritional satisfaction at the mother's breast with a minimum of effort and a maximum of immediate pleasure, a complete dependence combined with assurance of gratified desire. Its goal is the gradual lessening of the value placed on immediate nutritional satisfaction, an elaboration of indirect means of obtaining it, and a transforming of practical into more ideal ends, to be obtained only by hard continuous work. That is, the goal of self-preservation is economic independence, an adult who is able to wrest his living from the world by his own efforts and intelligence and who, at the same time is able to satisfy his creative energy. If he is tied to a dull unending round of labor and has no opportunity to move onward to the new, unconquered problem, he has not yet attained the goal, which is not just bare existence in the face of reality, but an actual forcing of reality to allow human growth and progress.

Dealing with Realities

As a baby the individual can get his wants supplied by crying. It is only as he finds himself wanting something that crying will not designate that he makes the effort to use other more elabo-

rate means. Since crying is not specific enough to indicate a certain object, he learns to use gestures. Little by little, as wants are not supplied by this omnipotent method, he tries to get some of the objects of his desire by his own efforts. At every step of the way, however, there is the temptation to use the earlier method, particularly when there seems to be no other way of obtaining ends. The most normal child may cry for the doll in the store window, if crying means a chance of getting it and he knows no other means. But the child who tends to cry first, and who holds on to this way of getting results, is not acquiring weapons for dealing with reality. He depends upon living in a child's world where a fond family can be influenced. He will find the world outside the family circle a hard place for which he is ill-equipped. We all of us know many adults who meet life on a similar plane. Difficult situations, instead of calling out the greatest intellectual effort to grapple with them, produce vomiting spells, attacks of headache, fainting, etc. Such methods are not conscious but instinctive; remnants of childish re-actions that were successful and easy.

Other individuals pass beyond this very primitive stage of self-preservation, which plays so safe that it hardly leaves infancy, but find the ease with which they can imagine satisfactions too great a snare. They want to achieve, to accomplish great results; as children they are always going to do fine things, but they are in too great a hurry for the outcome, they can't endure the delay and effort required to attain it in actuality, so they let an active and vivid imagination produce immediate returns which are so satisfactory that they may easily put off real fulfillment indefinitely. All of us more or less console ourselves in fancy for what we are unable to reach in reality, but the proverbial dreamer who accomplishes nothing is only the child who, fascinated by the power of thought, substitutes a dream for reality and is satisfied.

School a Crisis for the Child

School constitutes a crisis in the lives of all such children, since it demands of them effort and independence and does not respond to their regressive methods of dealing with reality. The child who finally adjusts himself to school conditions, however, may still find going out from school and the economic protection of the family circle into a world of work, a very upsetting, terrifying experience. Many young people who break down at this period show symptoms which seem to indicate a resistance to economic as well as sexual growing up. One youngster expressed it this way, "I simply can't endure the thought of

the long years of working ahead of me, doing the same thing day after day. I wish I had never grown up." A young Italian boy developed a new fear for every kind of job he tried. It was impossible to find anything in the way of work that had not something wrong with it. A girl who rebelled against maturity with all her strength developed physical symptoms which kept her at home whenever a position was obtained. Still another conceived a violent dislike of any trade or vocational training that was suggested.

We all know what it means, that resistance to giving up the ease and comfort of life at home and taking on responsibility for preserving one's own life. Children with such an aversion to independence need all the push forward, all the encouragement and strengthening of will that the family can give, and above all they need to be equipped with a definite something which they can really do well. The energetic individual, although he comes through high school or college with no particular training, can carve out a job for himself; but to the individual with the strong pull-back, lack of training for any particular work is a stumbling block which he overcomes only under the greatest pressure. Inability to face life on the economic side means delinquency in many cases, it means an overwhelming sense of inferiority in others which produces unpleasant neurotic symptoms. It tends to an unhealthy mental state and profound dissatisfaction with life, for such individuals must be forever concealing from themselves the fact of their failure. It is remarkable that girls in well-to-do families ever attain mental health with the pressure that is so frequently brought to bear to keep them at home, dependent on the father and mother. Add such environmental pressure to natural inclination and the result may easily be fatal.

Conflicts of Sex Life

So much for the self-preservation side of impulsive life. The other great trend which we may call sex, race preservation, or love life, exhibits a similar struggle in its efforts to attain the ideal of normal adulthood, intensified as it is by the extreme amount of repression and restriction put upon sex by the social environment. Sex instinct not only has its own internal conflict of safety motive with reality motive, but it has to meet social standards with which the individual always identifies himself at least in part, and in the face of all the existing restrictions still find expression for itself. Sometimes it seems as if society had done its utmost to make the path of sex development perilous, actually encouraging it to stop short of its goal.

Sex is not of necessity directed from the first

to another individual of the opposite sex. Such a going out of sex, leading to marriage and children, is the goal it tries to reach, but it travels a long journey and may stop anywhere on the way. Sex is the name we give to a certain imperative hunger or need of the individual. In its beginning it associates itself with certain bodily satisfactions and pleasurable experiences which are to be had independently of other individuals. The selfish, self-contained, limited idea of sex or love life is like the infantile dependence and omnipotence which we saw on the side of self-preservation. It can play safe and gain a certain satisfaction within itself without effort. It never need go outside of its own body. This, the psychiatrist calls the auto-erotic stage of love life, and it lingers with us as the regressive ideal of the safety motive, a possible resting place if the effort demanded for the next stage is too great, or if external conditions tend to drive it backward. We need always remember that the person whose sex life is driven back upon itself will most naturally and inevitably find outlet in infantile pleasures unless other use is made of the dammed up energy. The first attempt sex makes to lead the individual out of himself is in the attachment to the mother, who supplies bodily comfort and a warm, reassuring atmosphere of protection. This is perhaps the most alluring stage in the whole process of growing love life. It is capable of containing so much in the way of advancement and in development of personality, yet it requires so little courage, it is so altogether safe and wonderful, so satisfying, that it has been universally an ideal of the most perfect love, an ideal upon which to rest in time of stress or danger, the ideal upon which much of religion is founded. The physically weak or inferior child, the timid, retiring child, the only child, can hardly hope to escape from this stage unless he has a very disagreeable or a very wise mother. When, added to the child's own inclinations, there is the mother's need, using the child as an object for her own starved love life, he is, as it were, caught in a trap from which he will escape only by the grace of God.

The Adolescent Problem-Child

On the other hand, there are equally disastrous results if this stage of love life is unsatisfactory, if there is no supporting matrix of love and protection. The child is lost in a new and strange world, he has a deep-seated need for reassurance, a sense of social approval as necessary as the air he breathes. This craving for he knows not what, will lead him into strange and unwholesome paths unless he finds something to take the mother's place. One would expect to find many

disturbances from this cause among dependent children, who are thrown out of the supporting family situation into all kinds of alien places, changed from one place to another, perhaps many times within a single year. There must be some defensive reaction to environment on the part of such children, who have to live without the greatest necessity of childhood. It is probable that an investigation would show that dependent children in institutions and changing homes exhibit unusual attachment to forms of auto-erotic satisfaction, such as bed-wetting, thumb-sucking, nail-biting, interest in excretory functions and masturbation, or the more energetic forms of expression, such as stealing, romancing, truancy. These activities are expressions of fundamental hunger trying to satisfy itself in one way or another. The same thing would be true, of course, with any children whose home life was highly unsatisfactory.

Here again we have found the eternal paradox, mother-love must be the basis of the child's growth, but it must be overcome. The child who is to grow into an adult capable of meeting adult sex demands must be loosened from the tie that binds him first to the mother, then to the family. The forces that accomplish this result, aside from instinct itself which resists the home attachment, are the large family circle, brothers and sisters who break up the child's monopoly, school teachers, playmates, and all the interests and activities that take the child over from the smaller group. There is nothing more important in the entire life of the child than this broadening of social contacts, and enlarging of healthy activities. The child who has outside interests, who joins with other children in play, who takes hold of school with a will, has the best safeguard there is against the fixation of his love life on the mother or the family, which, if it occurs, may mean anything from lifelong unhappiness to mental disease.

The Struggle To Be Normal

When adolescence appears with its growing awareness of new physical needs and its need for the idealization of life and sex in the person of the loved one, if love life has been caught and held fast in an earlier stage, conflict begins. Auto-erotic habits interfere with normal sex life, yet offer no substitute for love, and there is a continual conflict between desire to be grown up and normal and the pull of the self-contained, easy, familiar path of pleasure. The awakening sex demands are repressed violently, where the young person's love life is quite completely fixed on mother, father, or other member of the family. There is no place for conscious sex in such a life

and if it is not used up in a variety of social interests and absorbing work, incest ideas will creep in and there will be perpetual conflict between instinct and the accepted morality of the group. Perhaps such an individual, in a struggle to be normal, may marry and find himself utterly unequal to the adult sex situation. His mother-attachment still holds him and tragedy or mental disturbance lies in wait.

So many paths there are for sex to wander in that there is hardly any object in life to which accident may not turn it. For instance, the child may get safely past the first two stages of his love life, without quite reaching the goal. Some blocking due to shocking association, or failure of the parents to meet the needs of childhood, may allow him to pass beyond the family but carry him no further than the individual like himself of the same sex. Endeavors to repress the sex elements in this tendency, sensitiveness to the attitude of society toward it, a tremendous desire to be like others, the difficulties of attaining any satisfactory sex life under such conditions, inability to meet marriage if it takes place: all of these factors combine to make the homo-sexual stage a dangerous stopping place, full of possibilities for delinquency, alcoholism, and many kinds of mental disturbance.

Effects on Social Welfare

This completes our skeleton outline of Everyman's life history, and because it is made up of never-ending conflict, it is also full of never-ending possibility of defeat to which we give all the varying labels that society has applied to maladjustment, criminality, delinquency, degeneracy, insanity, and the like, depending upon what effect the maladjustment has had upon social welfare. The hopeful side of the picture for the social worker is the apparent plasticity of growing human life. It permits of adjustment as well as maladjustment. Energy is not confined rigidly to any one outlet. If life denies one form of expression, another may be developed thereby to a degree hitherto undreamed of by the individual. If the social workers will approach the problem of her maladjusted children on the basis that the energy which is going into antisocial forms of behavior is detachable from such modes of expression, provided she can get at facts in the child's life and supply other satisfactory outlets, she will have taken the first step toward applying the dynamic psychology of the psychiatrist.

Before the granting of a marriage license in the state of Alabama, a physical examination is required of the prospective husband. He must undergo examination within fifteen days prior to the issuance of the marriage license.

THE NATIONAL BOARD OF MEDICAL EXAMINERS

BY WALTER L. BIERRING, M.D., PRESIDENT, IOWA STATE BOARD OF HEALTH; PRESIDENT, NATIONAL BOARD OF MEDICAL EXAMINERS, DES MOINES, IA.

THE idea of a central agency or board, to standardize and unify examinations for practitioners in medicine, has been the subject of discussion in medical sessions during the past two or three decades. Dr. J. M. Dodson of Chicago, in a letter to the *Journal of the American Medical Association*, September 1, 1906, was one of the first to suggest a National Medical Examining Board as a means to overcome the difficulties of interstate reciprocity. Colonel Jefferson R. Kean, M.C., U. S. A., contributed an interesting discussion with a definite plan at the Educational Conference in Chicago in 1914, but it was due to the enthusiasm and persistent reference to the subject by Dr. William L. Rodman of Philadelphia, that the National Board of Medical Examiners was finally established. It was the principal feature of his President's address before the meeting of the American Medical Association at San Francisco, in June, 1915, and its organization dates from that year.

Notable Men Are Members

Its membership, as originally constituted, consisted of six representatives from the three Federal medical services, and nine from the profession at large, three of whom were to be representatives of the Federation of State Medical Boards of the United States. The representatives from the Federal services included the three Surgeons General W. C. Gorgas, W. C. Braisted, and Rupert Blue, and, as additional representatives, Colonel Louis A. LaGarde, Admiral E. R. Stitt, and Surgeon W. C. Rucker of the Army, Navy, and Public Health Services, respectively. The remaining members from the profession at large, including the Federation, were Dr. V. C. Vaughan of Ann Arbor, Mich., Dr. Isador Dyer of New Orleans, La., Dr. Horace D. Arnold of Boston, Dr. Austin Flint of New York City, Dr. Herbert Harlan of Baltimore, Dr. William L. Rodman of Philadelphia, Dr. E. Wyllys Andrews of Chicago, Dr.

STANDARDIZED LICENSURE EXAMINATIONS

The examinations conducted from time to time in the medical centers of the country by the National Board of Medical Examiners, with the assistance of State Examining Boards, for graduates in medicine who are candidates for licensure, are the results of an earnest effort to embody the ideal of standardized and unified examinations for practitioners in medicine. A majority of the States, and the Army, Navy, and Public Health Service accept the certificates of the Board. The plan is being extended to other nations.

Henry Sewall of Denver, and Dr. Louis B. Wilson of Rochester, Minn. Surgeon General W. C. Braisted was elected the first president, and Dr. William L. Rodman of Philadelphia, secretary.

Very soon after its organization, the Board was called upon to mourn the loss of its distinguished founder, Dr. William L. Rodman, who met an untimely death from pneumonia, in March, 1916. To those who knew of his

devotion to the cause of a National Board of Medical Examiners, it is most gratifying that he was privileged to live to see it become definitely established; it thus became the crowning effort of his life, and will stand as one of his best monuments. As his successor Dr. Walter L. Bierring of Des Moines was elected. Dr. Rodman's son, Dr. J. S. Rodman of Philadelphia, was appointed secretary.

Upon the retirement of Surgeon General W. C. Gorgas by limitation of age, September 9, 1918, his successor, Surgeon General Merritt W. Ireland assumed his place on the Board.

In December, 1918, Dr. Henry Sewall of Denver resigned from the board. A successor has not yet been appointed.

By reason of its close relation to the Federal medical services, the National Board has been a prominent factor in bringing about a better mutual understanding of the medical departments of the Government and the general medical profession, which has been especially recognized in the recent war period.

Financial Support Is Adequate

The National Board, as a voluntary body, enjoys a distinct independent status, and, being supported by one of the large educational foundations, it is fortunately permitted to carry on its work free from financial cares to restrict its activities.

The principal object of the founder, Dr. William L. Rodman, that has been regarded ever since as the main purpose of the Board, was to develop

a plan of examinations for properly qualified graduates of medicine that would be indorsed and accepted by state medical boards in lieu of the examination for licensure required in their respective states. Doctor Rodman liked to refer to his own experience when, after being called from the University of Louisville to Philadelphia to assume a professorship in surgery, he was required by the then prevailing laws of Pennsylvania to take the regular licensure examination, sitting side by side with some of his former students from Louisville. The Board has reason to be gratified with the reception of the plan of examination by the state boards of medical examiners, since practically two-thirds of the boards in the country have already signified their acceptance and endorsement of the Board's certificate.

The certificate of the Board is accepted for admission into the Army, Navy, and Public Health medical services without further mental examinations. The Mayo Foundation will also accept as Fellows those who have passed the examination of the National Board.

The candidates represent the best type of graduates of medicine, since the requirements for admission to examination include a certificate from an accredited, four-year high school, two years of premedical college work, including at least one year each of chemistry, physics, and biology, and a reading knowledge of a foreign language, graduation from a so-called Class A medical school, and one year of intern service in an approved hospital.

Examinations in Medical Centers

The original intention of the Board was to hold its examinations in Washington, but it soon became evident that many desirable candidates were not able to come to Washington so it has become the policy of the Board, when necessary, to hold examinations in the larger medical centers and bring the same within close reach of the type of graduates, particularly the hospital intern, that the Board is desirous of interesting in this movement.

The first examination was held in Washington in October, 1916; the second also in Washington in June, 1917; the third in Chicago in October, 1917; the fourth in New York in January, 1918.

As the certificate of the National Board is accepted for admission into the regular medical services of the Army and Navy, it was thought best to hold several examinations in the Medical Officers' Training Camps, and, accordingly, an examination was held in April, 1918, at the Base Hospital, Fort Riley, Kas., and General Hospital No. 14 at Fort Oglethorpe, Ga. Since then the

seventh and eighth examinations have been conducted in New York and Chicago, respectively. An examination was held in Philadelphia during the first week of June.

While the original purpose of the foundation of the Board was to develop an examination that would be indorsed by the boards of medical licensure in the different states and territories of the United States of America, there has been a consistent effort to have the tests comprehensive and essentially practical, yet at the same time to be expressive and distinctive of the highest medical training in this country: and the intensive interest of representatives from the Federal medical services, and medical educators and examiners in the membership of the Board, with the assistance of medical teachers and State Board examiners as the examinations are held in the different medical centers, is gradually approximating to the above described ideal. With further experience changes no doubt will occur, but at the present time, it has seemed most satisfactory to begin the examination on a Wednesday and end on Wednesday of the next week, thereby having a Sunday in between for rest. It has seemed better to separate the surgical and medical divisions by having the tests in the subjects of applied anatomy, operative surgery, and surgical pathology, precede the clinical examination in general surgery and the surgical specialties: the practical tests in clinical chemistry, clinical physiology and pharmacology, general pathology, clinical microscopy, bacteriology, and hygiene, to be followed by clinical medicine; and practical obstetrics given separately. In each subject a short written examination is combined with the practical, which also includes a number of questions in medical jurisprudence. These are completed in six days, as no examination is held in the afternoon on Saturday, and one the last day.

In the Dominion of Canada there has been established for several years a Dominion Council which is similar in its purpose to the National Board. The Registrar, Dr. R. W. Powell of Ottawa, Ontario, was invited to attend the New York, January, 1918, examination, and submitted a most favorable report on the plan and character of the examination, besides giving a number of valuable suggestions which have since been carried out.

Colonel Charles Dercle, representing the French Medical Service in the Surgeon General's office during the period of our country's participation in the World's War, attended two of the National Board's examinations, and submitted a favorable indorsement in an official report to his Government.

In view of the intimate relations established between the allied nations during the great World's War, and particularly the mutual appreciation of the respective medical services, the Board considers this the opportune and psychologic time to familiarize the examining bodies of France, England, and Italy, with the purposes of the Board, hoping thereby to receive their endorsement, and thus lead the way to the international recognition of American medicine.

It has not been determined whether this can best be accomplished by sending a representative committee of the Board to visit the foreign examining boards, or to invite officials of the same to attend an examination in this country.

The executives and superintendents of the larger hospitals in this country, have manifested a deep interest in the purposes of the National Board, recognizing the influence of its examination in promoting a higher grade of hospital interns and practitioners of medicine. The members of the Board are deeply appreciative of the courtesies extended by such institutions as the Walter Reed, Garfield, and Soldiers' Home hospitals in Washington; Bellevue, New York, St. Luke's, Roosevelt, and Presbyterian hospitals in New York City; and Cook County, Presbyterian, St. Luke's, Michael Reese, Mercy, and Wesley hospitals in Chicago.

About one hundred certificates have been granted to successful candidates, including four women physicians. By the character of their work and the example of its examination, the Board hopes to live and fulfill its purposes, and thus add its mite towards elevating the standards of medical practice.

STATE AND PROVINCIAL HEALTH AUTHORITIES OF NORTH AMERICA

The thirty-fourth annual meeting of the Conference of State and Provincial Health Authorities of North America was held at Atlantic City, June 6 and 7, following the Conference of Health Authorities with the United States Public Health Service at Washington, June 4 and 5. Important committee reports were made on the following subjects: Activities in public health matters by Federal departments other than the United States Public Health Service; cerebrospinal meningitis; extension of Federal assistance in rural sanitation to the several states; progress of full time district health officer legislation; recent advances in sanitary laws, organization, and practice; the tuberculosis policy; international border health problems; and pneumonia.

Valuable contributions on the legal aspect of Federal health work were made by Dr. Frank A. Goodnow, president of Johns Hopkins University, and Allan J. McLaughlin, assistant Surgeon General, United States Public Health Service, the former on the possibilities and limitations of public health functions by Federal agencies under the constitution of the United States, and the latter on the

proper relation of Federal and state governments. Dr. Livingston Farrand, chairman, American Red Cross, gave a frank statement of the "Future Cooperation Between the American Red Cross and Public Health Agencies." The present status of pneumococcus vaccine was discussed by Russell L. Cecil, Major, Medical Corps, Army Medical School, and a symposium of health insurance and the public health was given by John B. Andrews, secretary of the American Association for Labor Legislation, George E. Tucker, Aetna Life Insurance Company, and John A. Lapp, managing editor of MODERN MEDICINE.

At the conference with the Surgeon General at Washington, problems of malaria, child hygiene, problems in interstate health work, public health education, problems in railway sanitation, the 1920 census, and the control of venereal diseases were discussed. Addresses were made by Judge J. H. Moyle, the Assistant Secretary of the Treasury, and Colonel W. H. Welch who represented the Public Health Service at the recent conference of Red Cross Societies held at Cannes, France, and Dr. D. Z. Dunnott, who serves as chairman of the Committee on Health and Medical Relief of the United States Railroad Administration.

HEALTH SURVEY IN ONTARIO SCHOOLS

A medical inspection and general examination for all the school children of the small towns and rural districts of Ontario has been arranged by the Minister of Education of the Canadian province.

Comprehensive plans have been made for the survey, which probably will extend over a year or two years' time. The arrangements provide for a dental inspection as part of the undertaking.

The Minister of Education, under whose direction the work will be carried out, has announced the appointment of some of the physicians and nurses who will assist in the project. The larger cities and towns which have made similar inspections will not be included in the present survey.

AMERICAN ACADEMY OF MEDICINE

The forty-third annual meeting of the American Academy of Medicine was held at Atlantic City, June 9 and 10, 1919, with the general subject, "War Problems of Sociologic Medicine," for discussion. The presidential address by E. O. Otis, M.D., Boston, discussed the effect of the war on moral values. Some of the important papers were: "The Needless Waste of Man-Power," by James P. Munroe, vice-chairman, Federal Board of Vocational Education; "The Effect of the War on Medical Education," by H. D. Arnold, M.D., Boston; "The Tuberculosis Problem After the World War," by S. Adolphus Knopf, New York; "Functional Nervous Disorders of Warfare in Relation to Employment," by Tom A. Williams, M.D., Washington; "Labor as an After-War Problem," by Irving Fisher, Ph.D., Yale University; "The Nation-Wide Plan for Venereal Disease Control," by C. C. Pierce, U.S.P.H.S.; "Housing in Relation to Health," by James H. McBride, Pasadena, Cal., which paper appears in this issue of MODERN MEDICINE; "Health Insurance," by Chester Rowell, Fresno, Cal.; and "Medical Attitude Toward Health Insurance," by J. B. McAllister, M.D., Harrisburg, Pa. The report of the committee on welfare insurance was submitted by George A. Hare, M.D., Fresno, Cal.

The papers and discussions at these meetings were of the highest merit in this field and should be widely read in their printed form.

PHYSICAL THERAPY IN FUNCTIONAL DISEASES

BY JOHN W. BOWLER, M.D., PROFESSOR OF HYGIENE AND PHYSICAL EDUCATION, DARTMOUTH COLLEGE, HANOVER, N. H.

TO DAY, more than at any other time in the history of the world, physical fitness and its importance are impressed upon our minds. In most instances physical unfitness should be considered as reprehensible conduct; for, after all, those who pay no heed to the proper care of their bodies and, because of their self-indulgences, often bring anxiety and unhappiness to their families and friends, are physical and moral sinners. A nervously tired-out man is not likely to inspire confidence in his business associate, client, or patient.

Mental staleness in the overworked business or professional man is like staleness in the athlete who has overworked in his desire to win, or because of overstimulation by an embryo trainer. A stale athlete never won a prize. Neither can a business or professional man with a tired-out nervous system or a stale mind carry to a successful issue anything that is really important.

Nature Is a Careful Creditor

If a man is tricky and dishonest, he can find some way to evade all his creditors but one; the one that cannot be beaten is Nature. Nature is indeed a kind and loving mother. Nevertheless her laws and demands are imperative. Because Nature is so lenient with most of us, we soon forget there are such things as laws of hygiene, and that the repeated violations of those laws bring their own penalty in the form of eventual ill health and, in many instances, of shortened or ineffectual life.

Nature's laws are mandatory. If not heeded early, her ultimate demands are likely to come in the midst of business enterprise when physical and mental health are prerequisites to success and the effort to resist this demand, or even to compromise, meets the usual result of things badly done if accomplished at all.

Practically all cases of mental and physical inefficiency are due, not to any organic lesion, but to a retention of waste products in the body caused by a lowering of the functions of the

THE TOLL OF BAD HABITS

The hustling American adds to his already heavy business or professional cares, in not a few cases, an assortment of habits bred of indulgence, haste, worry, over-work, dissipation, nervous tension, lack of exercises, and neglect of Nature's physical laws, which, at the end of a few years, will have seriously impaired the functioning of some one of the bodily organs.

Many of these patients, the tired business men who want to regain their old pep, may be restored to complete health by proper diet, regularity of habit, massage, and reliance on Nature's therapeutic agents.

however, would be a comprehensive answer to the question.

"For several decades preceding the war the death rate in the United States has steadily fallen, a phenomenon common to all civilized countries. This, however, has taken place in the younger age groups and not in the older age periods.

"This latter phenomenon, a rising mortality in elderly life, is something almost peculiar to the United States.

"England, Wales, Denmark, Norway, Sweden and Prussia show improved mortality at every age period.

"At age forty-five the death rate in the United States increased on account of degenerative diseases. In the United States the mortality from diseases of the heart, blood vessels, and kidneys increased 41 per cent, while in England and Wales there was a decrease during the same period from these same maladies."

Intemperances Raise Death Rate

Briefly, intemperance in most things is the cause which produces this dire result. But the subject is too important to dismiss in a brief manner, and it is the purpose of this communication to cite some of the most frequent causes of the degenerative diseases, and to suggest remedies or methods of treatment.

It is generally accepted, and correctly so, that the social diseases are responsible for a large percentage of the degenerative diseases; but there are many other causes which if not removed while in the incipient stages, lead to the same pathogenic conditions.

emunctories, principally the bowels, skin, kidneys and lungs; also, to a great depreciation in the functioning power of the liver, heart, stomach and intestines.

The predisposing causes which lower the functions of these organs might be summed up in the one word, worry. But what causes worry? Again the answer is in one word, pessimism. Pessimism sours the mind and degenerates the body." Wrong living,

The American is known the world over as a "hustler," a man of ceaseless energy. By some foreigners we are called a nation of neurasthenics. It is undoubtedly true that constant business cares and their accompanying worries are responsible for keeping men under constant high nervous tension, which in a short time reduces the functioning of all organs of the body.

The sporadic week-end spent at golf oftentimes does more harm than good, because of overindulgence and the inability of the body to throw off fatigue products so produced.

The general trend of late years has been to increase production efficiency, to speed up in every line of human endeavor even when this increase in efficiency is due, not only to eliminating unnecessary physical movements, but to improved machinery that requires the workers to speed up constantly in order to keep the machinery busy.

The busy physician, because of the automobile, visits more patients daily, and performs more scattered operations in a day now than he could do in two days a few years ago, but he actually spends less time in the open air and sunlight than in the days of the one-horse-shay. Likewise, the business and professional man does actually more work in fewer hours than was formerly accomplished in much more time. As this increase in accomplishment brings with it a corresponding responsibility, and, because of this, a higher, almost constant, nervous tension, why seriously express astonishment upon the increase in functional diseases?

Automobiles Cause Nervous Ills

The automobile performs a worthy function when it is used to take an invalid into the open air, where a change of faces, places, and scenery act as tonics. But how does it serve the average individual who has spent most of his daily hours at his business or profession merely of a sedentary nature? It lessens rather than increases the depth and frequency of respiration. A man riding in an automobile is practically at rest. This is not ignoring the fact that a passenger in an automobile riding even a few hours receives some slight direct and indirect tonic effect from the open air and sunlight, especially if he forgets his professional or business cares or worries. However, he leaves the car at the end of his trip with muscles somewhat stiffened, and with an appetite often increased beyond the requirements of the body; and this in turn causes increased ill health, because of the extra burden thrown upon the already weakened organs of digestion and inefficient organs of elimination.

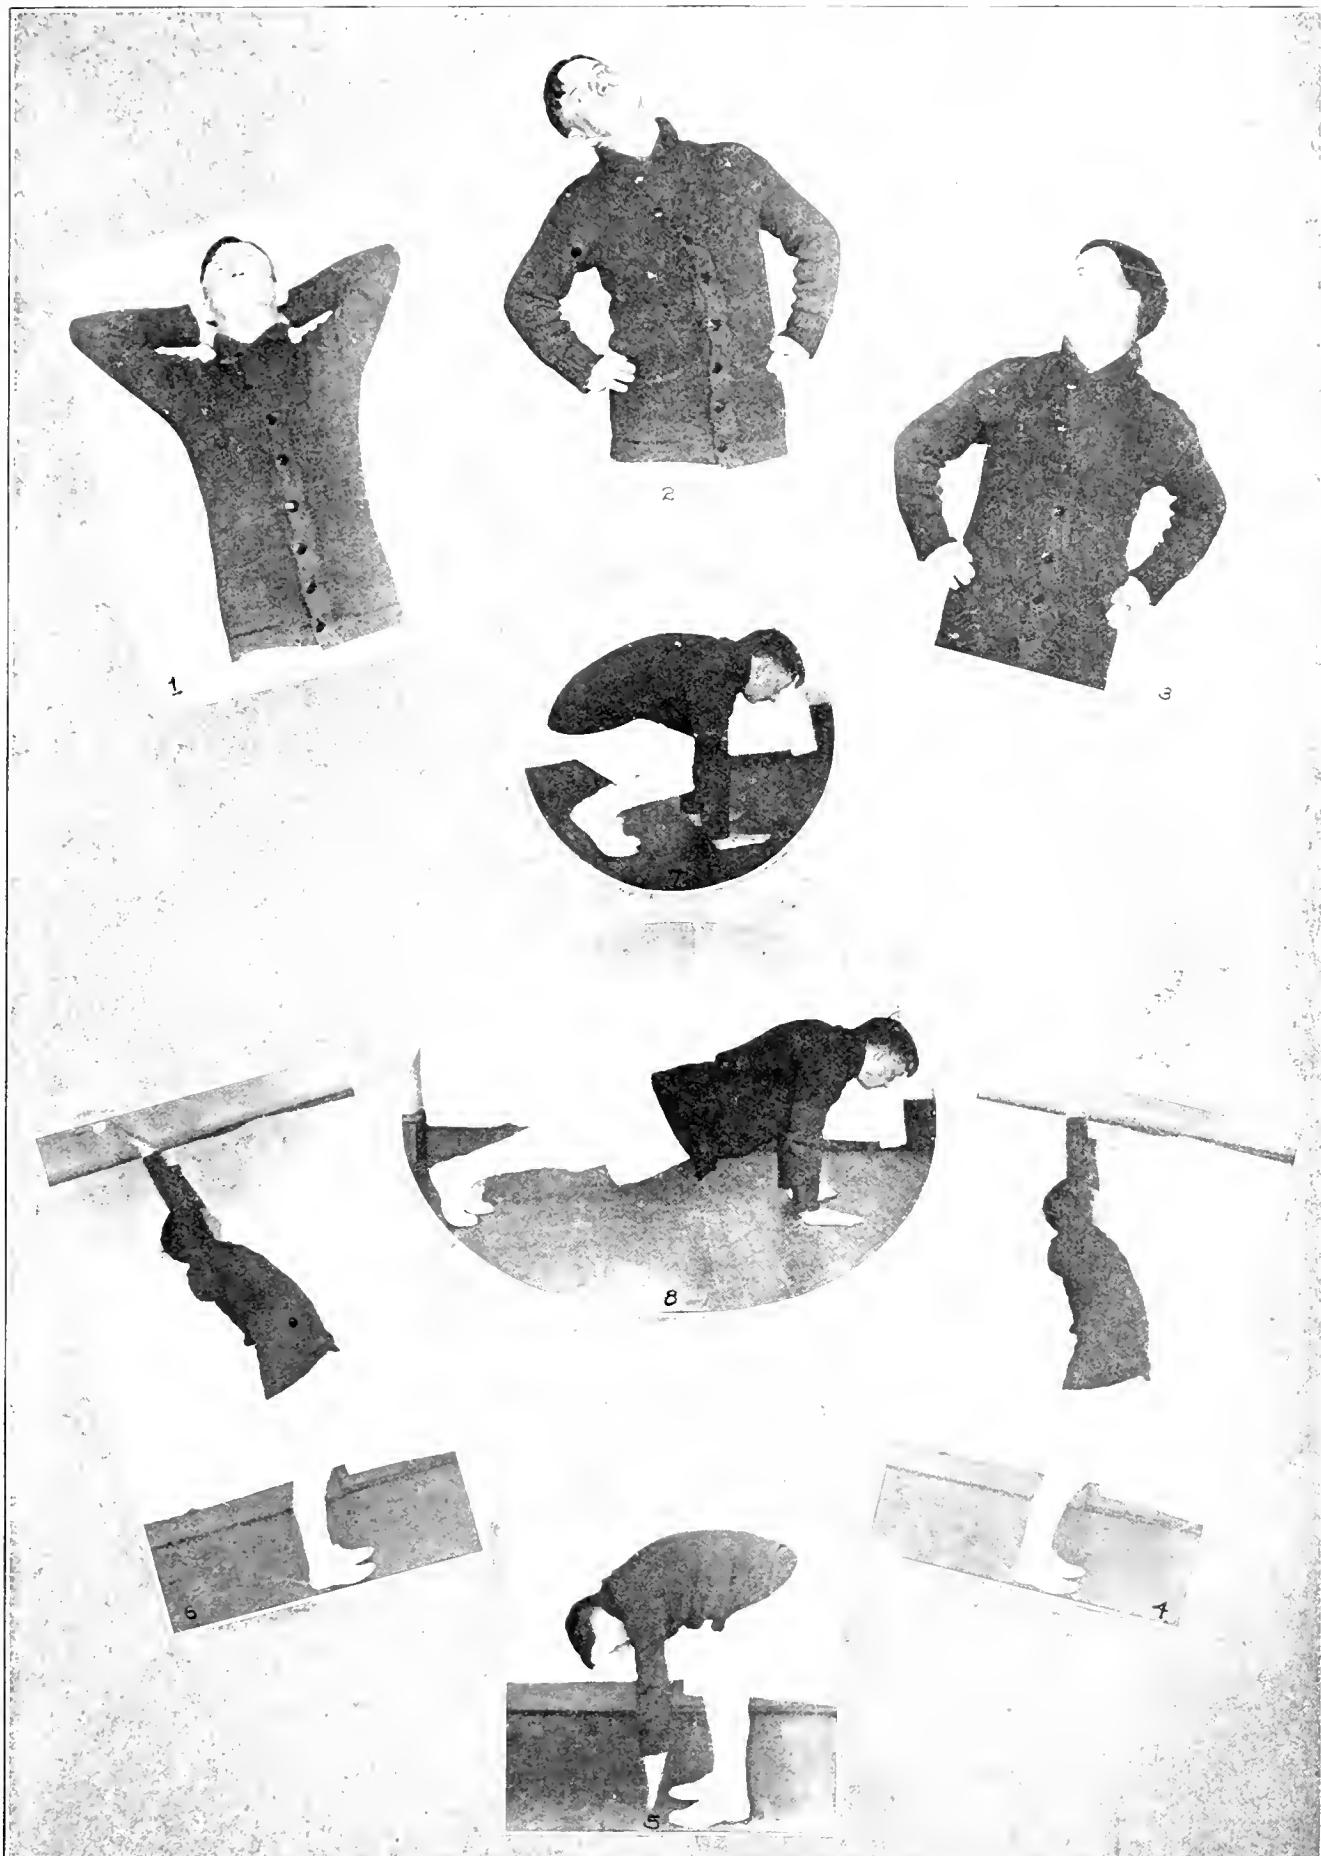

The various causes already mentioned as

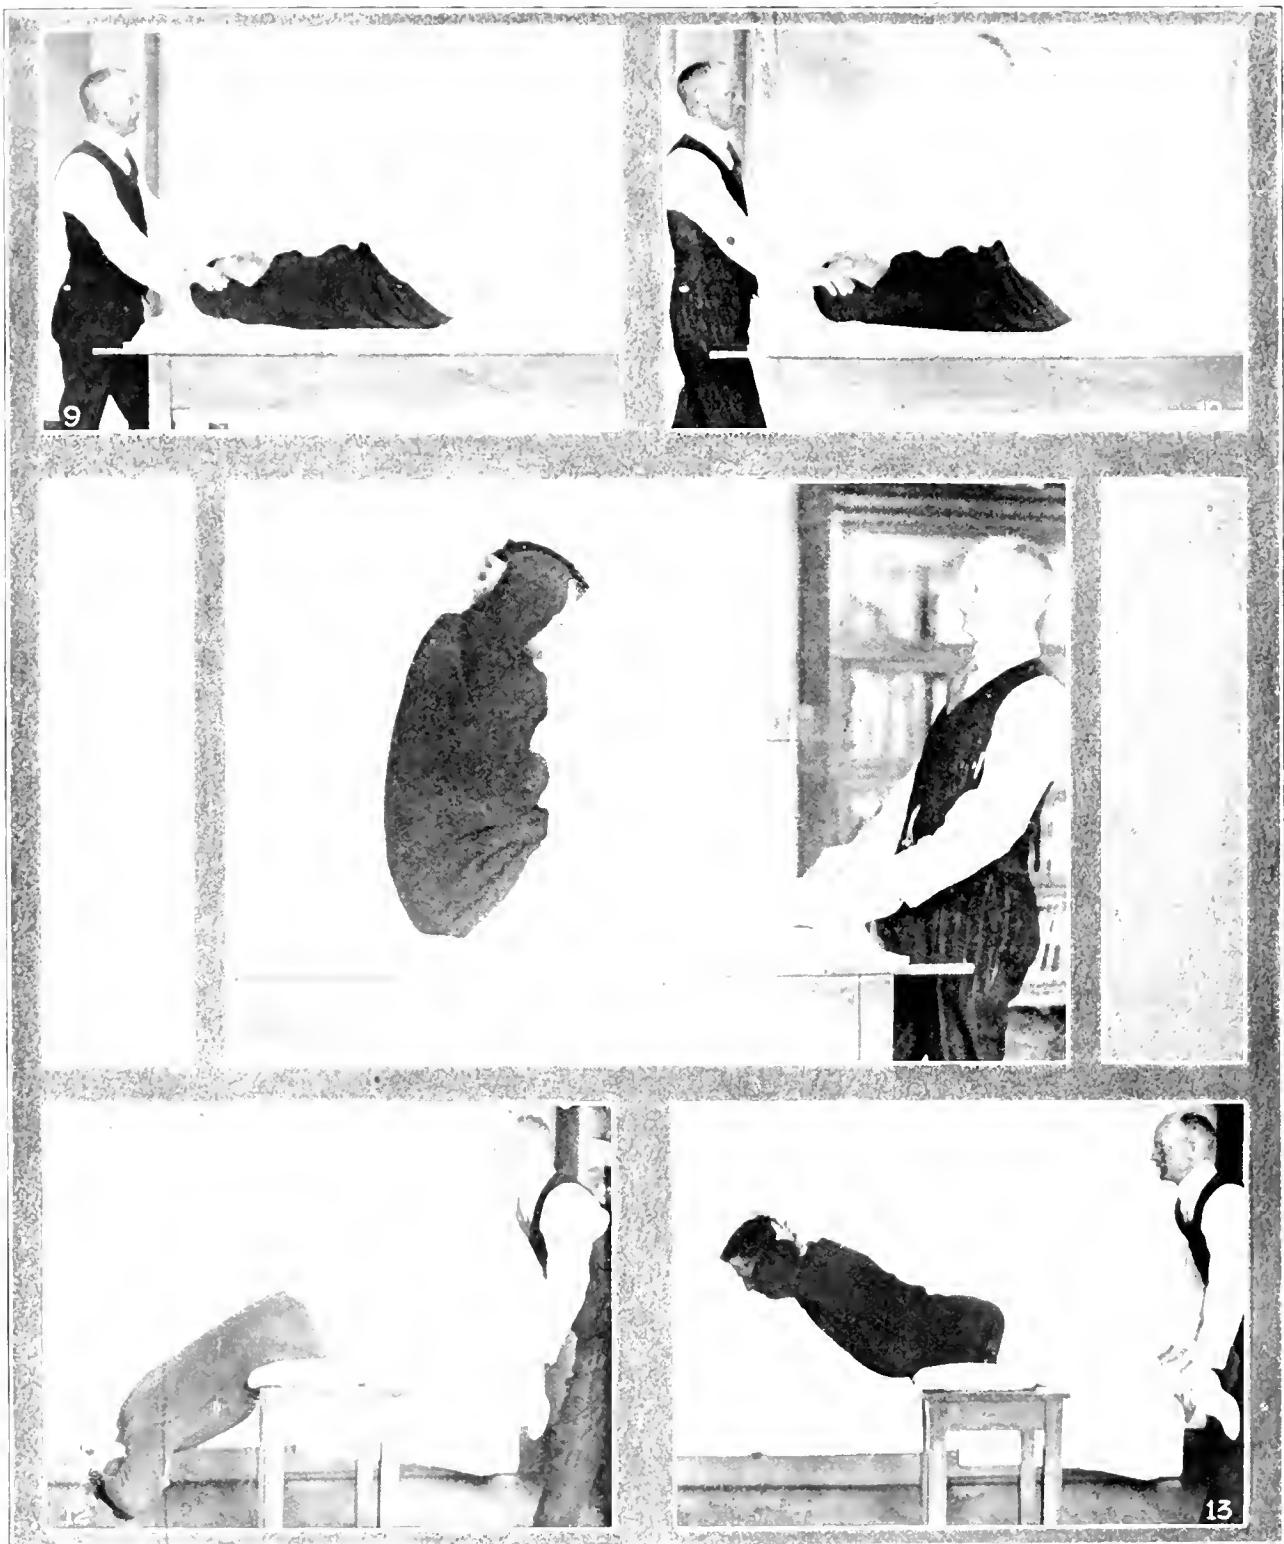

chiefly responsible for ill health among business and professional men will not be discussed. The causes of the nervous disorders among females are more various. Functional diseases in all classes and ages are met with among both sexes. Disturbances of the nervous system, aside from those resulting as the sequel of "social diseases," have for their etiology vicious daily habits, particularly in eating, drinking, in the matter of time and methods of recreation, and lack of physical exercise; and these disturbances are almost entirely restricted to business and professional men who add to their heavy cares and their corresponding worries those habits which are opposed to the laws of health and longevity.

If, then, the mind is to be an intelligent, efficient, commanding officer and the body a good soldier who obeys orders instantly and efficiently, both the commanding officer and the soldier who receives the orders are not only to be properly trained but properly cared for; otherwise when the time for the battle approaches the commanding officer becomes panicky and the soldier disorganized. When the battle actually takes place, chaos reigns and the affair ends in disastrous defeat. It is of little moment whether this battle is one for business, professional, political or social success.

When a patient presents himself to his physician the latter should be keen enough to read rightly the premonitory symptoms of overwork or wrong living, and have courage enough to inform his visitor frankly that stimulants or drugs of any kind are not the things needed to restore him to his normal, healthy condition. The so-called stimulant would probably act like the whip in the hand of a brutal driver whose horse halts exhausted half way up the hill. The driver may lash the horse again and again until the poor beast, stimulated by fear, makes a frenzied effort and goes on a little farther up the hill; but he will finally fall completely exhausted. Every drug stimulant has its reactionary, depressing effect, and these periods of depression become deeper and more frequent as the result of the stings of the stimulating lash until they merge into one continued period of depression.

I have referred above to premonitory symptoms, which are danger signals that should be heeded, which the patient as a rule endures for some time before consulting his physician. Work, which earlier was a genuine pleasure because of the delight taken in things well done, becomes increasingly difficult; less work is accomplished in a given time; memory is not strong, overlooks now and then some important matters; the

Some of the exercises devised for the treatment of functional diseases by the methods of physical therapy are portrayed in Figures 1 to 20, on this page and the pages preceding or following. A patient under treatment posed for the photographs. He began in a very poor general condition with a diagnosis of myocarditis. The exercises are arranged by series in the illustrations. A detailed exposition of the exercises employed in the treatment of the case, step by step, as illustrated, will be found on page 254.

NECK EXERCISES

Figures Nos. 1, 2, and 3 illustrate some of the movements of the head and shoulders that are used to secure an increase in the blood supply to the cervical section of the spinal cord and throughout the brain.

BENDING EXERCISES

In figures Nos. 4, 5, and 6 are pictured the bending movements of the arms and trunk

which the patient was told to perform for the effect in raising the chest wall and in increasing the antero-posterior diameter of the thoracic cavity, and also flattening the abdominal wall by bringing pressure on the viscera in assuming the stooping posture.

CROUCHING MOVEMENTS

A rather strenuous exercise is shown in Figures 7 and 8, as any one knows who has

tried the stunt which the patient in the pictures is executing. In the crouching position the pelvic and abdominal viscera are pressed upon and massaged.

EXERCISE ON A TABLE

By the increased oscillation of the viscera affected in the group of exercisers using the table, shown in Figures 9 to 13, a massage effect is gained, the fat about the viscera is decreased and the general tone improved.

patient is easily irritated, delays answering important letters because of indecision, and reaches a point where he tries to "side step" duties that are his to perform; his appetite is poor and he sleeps but little. By this time the patient is alarmed and consults his physician. Accompanying these symptoms will be found, through the history and a thorough physical examination, the inefficient functioning power of the emunctories and other organs and systems of the body. Why then further burden an already weakened, depressed, toxin-laden system?

Earlier in this article it has been stated that Nature's demands are imperative. Nature, however, usually gives ample warning and the man is indeed foolish who ignores the warning, or even tries to compromise. For if the danger signals are promptly heeded, health is more quickly restored with less loss in time and money and a corresponding diminution in the anxiety of the family and friends.

Observing the Patient

Now what are the best remedies to be used in these cases and the method of treatment? In order to carry out the treatment successfully the patient should be under the constant supervision of the physician who gives the treatments so that he may note and interpret, at intervals, the physiological reactions for a few hours subsequent to each treatment; also because many of this class of patients have lost their initiative and have not the power to go ahead with even the most carefully prepared type-written system of directions. Again, the treatment must be gradually increased in amount and intensity and this can only be done scientifically and efficiently under the personal direction of the one qualified to give the treatment and who is responsible for the result.

The treatment consists in establishing, by precept, regular and healthful habits and practical instruction in the laws that govern good health. Almost all these patients are restored to complete health in from three to six weeks.

In addition to proper diet and massage, Nature's therapeutic agents are entirely relied upon. Following is the daily schedule for the patient:

Rise at	6:30 a.m.
Five-minute stroll	6:55 a.m.
Breakfast	7:00 a.m.
Free time	7:30 to 9:45 a.m.
Treatment	9:45 to 11:45 a.m.

The treatment consists of special exercises, shower bath, sun- and air-bath (nude in the open air, weather permitting), and finally a thorough massage (not merely a rub). The exercises are increased as rapidly as the condition of the patient warrants, and the time devoted to massage lessened, until toward the end of the treatments not more than 15 minutes are devoted to massage.

Dinner	12:00 m.
Rest period	1:00 to 3:00 p. m.
Treatment	3:00 to 5:30 p. m.

The treatment in the afternoon is the same as in the morning with the exception of substituting a walk of 3 to 6 miles across country, through woods, and over hill and dale, for a portion of the special exercises.

Supper	5:45 p. m.
Recreation	6:45 to 9:15 p. m.
Bedtime	9:30 p. m.

The illustrations given herewith, (chosen from a long series of exercises because the easiest to photograph), may serve to make more clear the type of treatment. The impossibility of outlining a definite plan of procedure in the physical treatment of such cases is obvious to one who realizes that a physician who in such cases gives didactic orders, such as to walk a definite number of miles a day, does not appreciate the pathology of the condition, the observation of the reaction of the patient, the gradation of the work being of vital importance.

Before treatment is instituted, the patient is given a thorough physical examination to detect gross organic deficiencies. At the beginning the amount of exercise is carefully graduated according to the condition and the stamina of the individual, and this is gradually increased with the aim of producing healthful perspiration, good cardiac and pulmonary action, and raising the general tone of the entire body.

Treatment and Method of Procedure

The schedule given above is carried out to the letter; thereby regular habits are developed. The first day the part devoted to physical exercise may not be more than fifteen minutes. The exercise consists mainly of calisthenic exercises so arranged as to bring into play every group of muscles and to stimulate the viscera and all organs of the body. After this the patient is given a shower bath and, weather permitting, he then steps, nude, out on a balcony where he receives a sun- and air-bath, gradually increasing from ten minutes to perhaps half an hour. The treatment is concluded with a general massage for about thirty minutes.

The afternoon treatment begins with a walk, moderate as regards both speed and distance; this is gradually increased. The day is completed with the exercises as given for the morning treatment.

The first week is a period of marked transition and during that period the exercises are increased in intensity and length. After the first week from one hour in the morning to two hours in the afternoon are occupied with this alone. Later, when advisable, more vigorous competitive exercises are added, such as a tennis, hand ball, etc. Before, during the exercise period, and after the complete treatment has been given, the pulse and heart action are noted and the treatment modified accordingly.

Practically all the patients for reconstructive treatment are afflicted with chronic constipation and by the measures outlined the normal functions of the intestinal tract are quickly restored without resort to cathartics. A large proportion of the cases are business and professional men who are nervously worn out and all of this class of patients are restored to complete health and renewed courage. Details are given of four patients who presented definite organic lesion.

A. Man, age 52. Came with a diagnosis of interstitial nephritis. Blood pressure 226. Nervous. Treatment lasted 12 weeks. Blood pressure reduced gradually until the ninth week, when it was 146, at which time the urine was normal and remained so. Absolutely no sign of nephritis and none on examination three months later excepting a blood pressure of 152.

B. Man, age 22. Rejected in June, 1918, by his local examining board because albumin and casts were found in the urine. Height 5 ft. 9 in. Weight 120 pounds. General condition bad. Left in good condition after 10 weeks' treatment, having gained 15 pounds in weight. Urine normal. On reexamination in Chicago he was accepted for military service and sent to an officers' training camp where he remained until the armistice was signed.

These are the only two cases of nephritis so treated. Whether such cases are true nephritis or essential hypertension will need to be determined by the internal medical men. Treatment was undertaken with the hope that neuromuscular training would improve the general physical condition and thereby increase elimination through the lungs, bowels, and particularly through the skin, by increased respiratory action and profuse perspiration, and the massage effect on the bowels by graded and scientifically applied physical exercise. The only change in the diet was a slight reduction in the amount of the dark meats. General improvement was expected, but the marked benefit to the kidneys of the treatment in both cases has furnished food for thought. The results are reported at the instance of interested physicians.

C. Man, age 41. Height 5 ft. 7 in. Weight 220 pounds. He came with a diagnosis of cholelithiasis on the advice of his surgeon to get into better condition before operation for removal of the gall-stone. After two weeks' treatment at Hanover, and four at "Health Farm" he was reduced 46 pounds in weight, was in perfect health and has remained so for a period of two years.

D. Man, age 79. Came to farm with a history of angina pectoris, chronic indigestion, and chronic constipation of many years standing. For the relief of the constipation the patient had resorted to enemas for several years. Treatment was much modified in this instance and was directed almost entirely to the relief of the conditions of the stomach and intestinal tract. The second day the patient had two normal stools and this continued during six weeks of treatment. The "angina" attacks became less severe and less frequent, and in a few weeks the patient was entirely free from heart symptoms. Close observation of this case would seem to indicate that it was not a true angina for the attacks entirely disappeared as

the functions of the stomach and intestinal tract approached the normal. The patient returned to the farm a year later for four weeks' treatment and left, age considered (80 years) in excellent condition.

EXPOSITION OF EXERCISES IN PHYSICAL THERAPY

The accompanying illustrations show some of the exercises applied in the treatment described in the foregoing pages. The subject is a patient now under treatment. Patient came with a diagnosis of myocarditis, and, in very poor general condition. Age 50. Blood pressure (diastolic) 98. Heart weak and arrhythmic. Lung capacity but 180 cubic inches. Chest expansion but 1.4 inches. Girth of chest, fully expanded, 35.3 inches. Girth of waist 36 inches. Height 5 feet 4½ inches. All measurements, except girth of waist, below the average. Muscular strength and coordination very poor. Distention of the intestinal canal, particularly the colon. End of first week's treatment, general improvement good. Blood pressure 108. End of second week's treatment improvement marked. Blood pressure 112. Lung capacity increased 20 cubic inches. Chest expansion increased ¾ inch. Girth of chest increased 1 inch. Part of the latter is due to increase in the muscular tissue and in part to increased elasticity of the chest wall. Girth of waist shows a decrease of 1½ inches.

* * * *

[The following brief explanations of the execution of the few exercises illustrated, and the physiological results attained will make clear the value of gymnastic exercises as a therapeutic agent.]

SERIES NO. 1

Fig. 1. Fingers interlaced, hands behind occiput, press the head backward resisting with the hands; then carry the head forward; repeat about twenty times.

Fig. 2. Hands on hips, flex the head toward the right shoulder; then lift the head to erect position; repeat about twenty times. The same movement is then executed toward the left shoulder.

Fig. 3. Rotate the head looking over the right shoulder as far as possible, about twenty times. Repeat to left.

The effect on the various groups of muscles used in the execution of the above exercises is obvious. The principal physiological action sought for is an increase of the blood supply to the cervical section of the spinal cord and throughout the brain.

Increased use of a group of muscles adds to their size and efficiency. The speed, strength, ease, and grace of coordination between the various muscle groups are merely physical manifestations of the degree of nerve power the individual possesses. Through the increased use of a group of muscles, the efficiency of the nerve cells of the spinal cord and brain, and the nerve fibers which form the connecting link, is increased. Metabolism is improved, and elimination of waste products accelerated.

SERIES NO. 2

Figs. 4 and 5. Arms extended overhead, bend forward and touch the toes as in Fig. 5, keeping the lower limbs straight. Swing upward to starting position and repeat. This exercise is done from one to two hundred times daily, in the two treatments given.

Figs. 6, 7 and 8. Arms extended high overhead. Swing forward and downward to position as shown in Fig. 7, and on count 2 extend the lower limbs and body in a straight

line backward as in Fig. 8, and on count 3 return to position as shown in Fig. 7, and on count 4 arise to erect position as in Fig. 6. Repeat this exercise as often as advisable.

The effect is to raise the chest wall and to increase the antero-posterior diameter of the thoracic cavity, to flatten the abdominal wall and bring pressure on the abdominal viscera in assuming position as in Fig. 6. In position 7 the pelvic and abdominal viscera are pressed upon and

massaged, and released from pressure on assuming position 8, and the effect again brought on the viscera on returning to position 7. The effect on the muscles is obvious.

SERIES NO. 3

Fig. 9. Lower limbs extended in line with body, flex the thighs against the lower abdomen, then return to straight position and repeat.

THE BAR-BELL

The exercise with the bar-bell illustrated in Figures 14, 15, and 16 stimulates the liver in particular, and, by the massage effect gained in rotating and bending the trunk, improves greatly the functioning of a sluggish liver. The massage effect along the spinal cord and nerves is beneficial in cases of neurasthenia. The fat about the abdominal viscera, as well as the external fat about the waist line is reduced. The exercise shown in Fig. 16 is used for the same effect.

THE DUMB-BELLS

Figures 17 and 18 show an exercise with the dumb-bells in which the bells are swung outward and downward, while at the same time the squatting position is assumed and the bells brought forcibly together behind the legs as low down as possible. Then the body is quickly straightened and the bells swung outward and upward. The effect of this exercise is in the muscles of the chest, shoulders, and back, and the massage upon the abdominal viscera.

THE MEDICINE BALL

An exercise with the medicine ball is shown in Figures 19 and 20. The ball is held in position in front of the chest. The movement begins by thrusting the ball outward and downward, between the feet, as far as possible, a movement which crowds the abdominal wall. Then it is swung forward and upward, ending the swing of the ball behind the head. The ball is then thrown to the assistant, or to another patient. This exercise is repeated from ten to fifty times.

Fig. 10. Retain the extended position of the lower limbs and raise to a right angle, at least, to the body.

Fig. 11. Raise the body to a sitting position and return to the recumbent posture.

Figs. 12 and 13. Using a small table, bench, or stool, with a folded blanket slightly overhanging the edge, have patient assume position with assistant holding the ankles as in picture 12. Patient raises the body to position as shown in Fig. 13 and repeats.

By the increased oscillation of the viscera in exercises 9, 10, 11, 12 and 13, a massage effect is gained, the fat about them is decreased, and the general tone of all the viscera increased. The fatty tissue about the abdominal wall is decreased and the muscles made firm and increased in size and strength. The functions of all the organs, in particular the stomach and entire intestinal tract, quickly approach the normal functioning power of healthy organs. Many patients when beginning are unable to accomplish exercises 10 and 11 even once, but within a week are usually able to repeat those exercises from ten to twenty times, without a break in the rhythm.

SERIES NO. 4

Figs. 14, 15, and 16. With a bar-shell as shown in Fig. 14 (a long push-broom handle will answer the purpose) flex the body to the right as far as possible as in Fig. 15; then, rising to erect position, flex to the left side; repeat fifty times. Then from the erect position rotate the body to the right side looking around as far as possible; then swing through the front to the left side as far as possible fifty times, as shown in Fig. 16.

After a few days the patient will do each of these two exercises from two hundred to five hundred times daily, depending upon the condition of the patient and what it is desired to accomplish. The exercise as shown in Fig. 15 stimulates the liver in particular and by the massage effect considerably improves the functioning of a sluggish liver. Other viscera are also benefited. The massage effect along the entire spinal cord and the spinal nerves is markedly beneficial particularly in cases of neurasthenia. The fat deposited about the abdominal viscera, as well as the external fat about the waist line, is reduced. The exercise as shown in Fig. 16 is used for the same effect but the attack is made from a different angle.

SERIES NO. 5

Figs. 17 and 18. These figures show one of a large group of dumb-bell exercises. It is started as in Fig. 17. The bells are swung outward and downward, describing as large a radius as possible; at the same time the squatting position is assumed with the abdomen pressed on the thighs and the bells are brought together forcibly behind the legs as low down as possible. Then the body is quickly straightened and the bells swung outward and upward. The ends are brought together overhead and the whole manual repeated.

The particular effect of this exercise is upon the upper chest, shoulder, and back muscles, and the tremendous massage effect upon the abdominal viscera.

Figs. 19 and 20. These figures show one of the medicine-ball exercises. The ball is started from in front of the chest and swung outward and downward between the feet as far as possible, crowding the abdominal wall, then swung forward and upward, ending the swing of the ball behind the head; then the ball is thrown about 20 feet to the assistant, or to another patient. This exercise is repeated from twenty to fifty times, depending on the strength of the patient.

LAMBERT REVIEWS MEDICAL PROGRESS

The presidential address of Alexander Lambert before the American Medical Association at Atlantic City is a notable contribution, summarizing particularly the work of the medical association during the World War and deducing from this survey the outstanding problems of the profession to-day.

It was no small achievement for the profession to meet within a year conditions demanding the expansion of the medical corps of the army and navy to something like thirteen times its personnel in times of peace. This rapid mobilization would have been physically impossible but for the excellent organization of the American Medical Association and its rapid dissemination of all important news through the pages of its valuable journal. That physicians would at once respond to the demands upon them was to be expected of a profession whose very nature presupposes a body of chosen men, men of high purpose, disciplined by habits of scientific study, and dedicated to the service of their fellow men. That this mobilization of medical forces required 26 per cent of the entire profession of the country is evidence of the great personal sacrifice it entailed. This sacrifice and the achievements for the welfare of the men should reflect full credit on the medical corps and should result in legal enactment which will bring about adequate representation of the Medical Department on the General Staff of the Army.

His study of the medical history of the several wars gives startling confirmation of the needless waste by disease of armies and peoples.

Scientific medical research has resulted in the practical elimination of many of the scourges of former wars. The crucial test of preventive medicine in the recent war is not fully realized. It is no longer inevitable that pestilence among civil populations must follow demobilization of troops. Proper sanitation, preventive inoculation, disinfestation, have removed this danger. The pneumonia of the recent war was beyond control, being a part of the world epidemic; but, eliminating the pneumonia death rate from the total death rate by disease in the war, there remains a rate of 2.2 per thousand for the entire army on both sides of the water, which is practically a peace-time rate.

The discussion of the relative incidence of the several infectious diseases is full of interest and serves to emphasize the necessity of placing the initiative of certain provisions for the welfare of the men in the medical department of the army. He discusses other outstanding needs of broadened educational facilities for medical men; of organization problems bestowing authority according to responsibility, and proper correlation of clinical procedures so that uniformly good care may be given to all; of the advisability of an established policy delegating to the Red Cross certain functions they have performed well in an emergency.

One need which stands out with great distinctness is the importance of general national supervision of public health through protection against transmissible diseases, of Federal measures of wide scope in the prevention of malaria, for instance, of central action on problems of health education, some phases of infant mortality, and on the increase of degenerative diseases. This is a period of unprecedented health activities but they "lack the efficient power of central correlation. . . . It is the duty of the American Medical Association, and of each member of each state association, to urge on Congress the establishment of a National Department of Health.

THE NEED OF SPECIAL CLASSES FOR CHILDREN WITH DEFECTIVE SIGHT

BY JOHN GREEN, JR., M.D., F.A.C.S., ST. LOUIS

THE daily routine of the practising ophthalmologist may appear to some of his fellows a rather dull, not to say tedious, round of oft-repeated duties. One who really cares for his specialty will, however, always find enough variety to incite his diagnostic and therapeutic acumen. The ordinary problems of any medical practitioner confront him, in addition to many questions which pertain strictly to his special sphere, and it would seem that to an exceptional degree the wider reaches of medicine, the study of the patient and the application of remedial measures according to economic and social need, are more urgent upon the ophthalmologist than upon other specialists. Often, indeed, the question is not one of diagnosis and treatment, but of social study and adjustment. The truth of the hopeless blindness of a child may have been dimly realized by the parent, and the appeal is not so much medical as social, the consultation being sought in the hope that some means may be suggested to lighten the almost intolerable economic burden of blindness.

Compulsory Education for Blind

More than any other class of unfortunates, the blind make their sympathetic appeal, and organized work for their relief provides in the United States (1916) 61 public schools for the blind in which 5,155 pupils were enrolled. Surveys have been taken, appropriations made, standardized methods of procedure established and, in some states, the education of blind and deaf children has been made compulsory. It is the plain duty of the oculist consulted to be fully informed as to the details of the work of his state institution so as to be able to urge with all eloquence that the stricken child be entered there at the earliest opportunity in order to give him every chance to acquire a thorough education. Only those who have been privileged to watch the emergence of

EDUCATION OF THE SEMI-SIGHTED

The standard methods of classroom study in the public schools are unsuited to the child with poor sight.

For him there is either no education adapted to his handicap, or else education acquired at the expense of untold nervous strain.

Special classes and methods are needed to give the visually deficient child an equal chance with his better equipped playmates. Surveys have been made and standards developed for the education of the blind. The same wise procedure should be adopted in the education of the semi-sighted.

the shut-in soul from spiritual darkness to spiritual light through the kindly and highly specialized efforts of schools for the blind can realize the immense good that these institutions are doing.

"There are 100,000 men, women and children in this country who are, within the strict definition, blind. One-fourth of these need not have lost their sight.

. . . This means the loss to the State of productive labor," and

shows the economic importance of vocational training for the blind.¹ The conservation of vision of the partially sighted is even more important. The prevalence of defective vision is indicated by the rejection of 12,374 persons on account of deficient eyesight out of 166,392 recent applicants to the Navy and Marine Corps. The possibilities for good in early reclamation work are indicated by the 1917 survey of 29,242 blind persons in the United States which elicited the fact that of the total group only 6.6 per cent were born blind; 5 per cent lost their vision before the age of one year, 16.4 per cent under the age of five years; 30.8 per cent under 20 years of age; 47.4 per cent during early or middle years (from 20 to 64 years, the increase being due to industrial accidents, etc.); and 21.8 per cent (about one-fifth of the total group) after the 65th year. Ocular examination of school children should be universal and should be repeated regularly so as to determine as early as possible the causes of defective vision during school life and to see that the rules of visual hygiene are observed. Recent figures from Ohio show 538 children with defective vision and 332 with diseases of the eye in 1,680 school children examined. A survey in Chicago showed 65,000 pupils with defective eyesight, 660 with vision less than one-tenth normal. Considered by grades, this defective vision became apparent in the first grade; reached 32 per cent in the second; was lower in the third, but was 24 and 25 percent respectively in the fourth and

¹ De Schweinitz, G. E., Jour. Am. Med. Assn., xvi, 393-97.

fifth grades; was higher in the sixth, and reached 30 percent in the seventh and eighth grades. Recent records of the Child Hygiene Division of the Department of Health in Chicago show that out of 141,811 school children examined for physical defects, 25,299 were found with impaired vision.

The myopic or near-sighted child without glasses struggling to read the ordinary textbook.

of this number, 14,548 cases were so serious as to require attention and treatment. This was a local survey, but the numbers are sufficiently large to justify the conclusion that all those with defective vision should be favored in the public schools by special methods which shall conserve rather than diminish the remnant of vision which these children possess.

We are justified in assuming that in every community there is a group of children with irredeemably defective sight who cannot profit by educational methods suitable for their full-sighted companions. Sometimes the visual defect is not discovered in infancy and early childhood. The child avoids obstacles, plays with its companions, and takes an interest in toys and picture books. He may have enough vision to struggle through several of the earlier grades, but sooner or later it is brought home to the parent or teacher that the child is suffering from an ocular handicap.

Let me briefly relate three cases which have recently come under my observation—cases which brought home to me this serious problem and left me helpless when I came to cope with it.

Case 1. A little girl, aged 9, was found to have a great deal of difficulty in reading; she would hold the book close and at an angle. Nor could she tell what the teacher placed on the blackboard. One optician and two oculists had prescribed glasses. Apparently no explanation had been offered of the reason why glasses failed to relieve. A glance at the eyegrounds showed in the center of each macula retino-choroidal atrophic spots. What little vision this child had was eccentric, and hence not useful for any very fine visual tasks.

Case 2. A boy, aged 12, was brought because his eyes

"rolled round" and because he had "white spots on his sight." After five years of schooling he was still in the second grade. The history indicated that he had suffered from ophthalmia neonatorum. He had the usual sequelae of a neglected case of this disease—an adherent leukoma covering the pupillary space in one eye, a nearly central corneal nebula in the other. There was marked nystagmus. R. V. 20/60. L. V. fingers at 2 feet. All possible combinations of glasses were tried without benefit.

Case 3. A little boy, aged 8, is a partial albino. He has the usual ocular characteristics of this anomaly—light blue irides, great deficiency in retinal pigmentation, and nystagmus. Vision 20/60, either eye. Tinted glasses correcting his hyperopic astigmatism were helpful in the sunshine, but there was no improvement in vision.

What constitutes defective sight? No hard and fast line can be drawn between the sighted and semisighted on the one hand, and the semisighted and the blind on the other. For purposes of classification, defective sight has been defined as "vision not more than one-third nor less than one-tenth with the best glasses obtainable." There are a variety of causes of poor vision, e. g., congenital cataract, retinitis, optic atrophy, etc. Many children with high hyperopia and progressive myopia cannot be made to see well with their correcting lenses and should properly be included in this group.

Children suffering from ocular defects of this sort have, of course, always been enrolled in every large school system. Prior to the period of medical inspection, the reason for the backwardness of any given child did not always appear. All that the teacher and parent knew was that the youngster did not get along well. Even if the defect were discovered, the teacher and parent were

With corrective glasses she has less difficulty.

helpless. The former had no right to exclude such a child from classes and often tried hard to fit the child into the usual educational groove—a process which was no more successful than the attempt to fit a square block into a round hole. At the end of the term the discouraged teacher

had no recourse but to demote the discouraged pupil. The following year the same weary and futile process was repeated. Of course, this sort of thing could not keep up indefinitely and the problem solved itself (if solution it can be called) by the child leaving the school long before completion of the grammar school grades.

When systematic medical inspection began to be the rule in schools in the larger cities, more and more of these cases came to light and the problem began to assume definite shape in the minds of educators. It having been determined that these children could not be educated in the ordinary schools, it was thought that provision might be made for them in schools for the blind. It was assumed (erroneously, as experience proved) that the partial sighted child was to all intents and purposes a blind child, and that the educational methods appropriate for the latter would prove equally effective for the former. This experiment was tried out, for example, at the Perkins Institution for the Blind in Boston; but it was foredoomed to failure. The child's vision may be seriously defective, and yet he sees after a fashion. He is bound to rebel at any effort to fit him into any educational system designed for the sightless.

In the education of the blind the lost sense of sight is replaced by the sense of touch, and to some extent by the senses of smell, hearing, and taste. Many of us endeavor to accomplish by touch alone tasks that usually require the cooperation of eye and hand. The beginner in knit-

"touch typewriting." But perhaps, after all, sight does prove an adjuvant to touch to a degree that is little suspected. It may seem to the experienced knitter or typist that she is wholly independent of vision; but, as a matter of fact, there occur moments of hesitation or uncertainty

This is her brother, who was considered a defective delinquent in the ordinary grade but now that he can see to do his school work is proving himself a good student.

when the sense of touch is deemed inadequate to obviate an impending mistake, and then a lightning glance will insure the correct completion of the task. The same irresistible tendency to supplement by sight the tasks supposedly carried on by touch alone is shown by the partial-sighted when the attempt is made to instruct them by methods suitable for the wholly blind. For instance, it has been found impracticable to teach the raised types of the blind to partial-sighted children: the laborious process of determining the individual letter by the sense of touch is soon abandoned and these children are found straining their eyes in an effort to *see* the arrangement of the raised dots. Thus is promoted the very thing which should be avoided: namely, overstrain of the eyes.

To Segregate Is Mistake

One of the disadvantages under which the totally blind child labors is that as a rule he has received his education in a special school away from contact and association with his sighted fellows. This drawback has been recognized and in some places, New York, for instance, many blind children are educated in the schools for the sighted. New York's experience has been so favorable that other communities have followed suit.

Classes for semisighted children should always be conducted in the regular school buildings, as much of the instruction can be given in the regular class room. During recess the semisighted children are encouraged to mingle with their

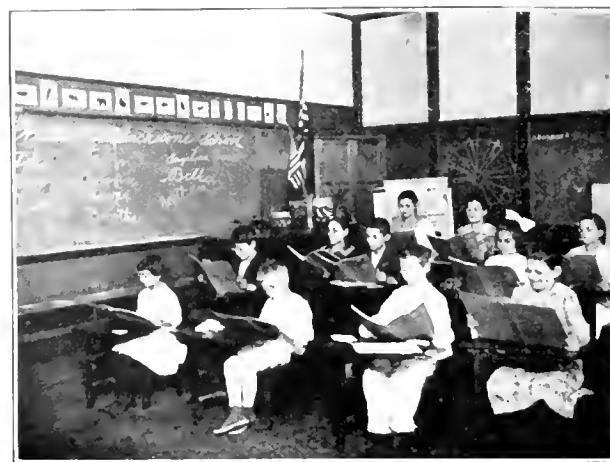

She is now receiving her education in a sight-saving class, where she has an adjustable desk and large typed textbooks.

ting finds that sight and hand must be helped out by mental concentration (and sometimes by facial contortions); but with practice the mind is less and less concerned with the task and finally the fingers do the work with hardly a glance from the eyes. So it is with one who has learned

full-sighted companions and are allowed to indulge in games and play of the less vigorous sort, thus affording every opportunity for contact with the normal sighted, and avoiding undesirable segregation.

I am indebted to Miss Ida E. Ridgeway, super-

Reading lesson with large-typed books in one of Boston's sight-saving classes.

visor of Work of Children, Massachusetts Commission for the Blind, for the following statement concerning schools for the semisighted in this country and abroad:

"In 1905 Germany established the first special class for this type of child. About two years later England, also, established classes known as 'The Classes for Myopes.' The first class in the United States was opened in Boston, April, 1913, and still continues its usefulness in the annex of the Abbe May School in Roxbury. Soon after this, Ohio established several sight-saving classes. I believe they now have eight. In November, 1915, New York City segregated a group of children who were being taught in the public school classes for the blind, this experiment justifying the establishment of eleven such classes at the present time, eight in Manhattan and three in Brooklyn. A class of this sort is about ready to be opened in Rochester, N. Y. In Massachusetts we have nine classes, four under the Public School Board of Boston, two in New Bedford, one in Worcester, one in Cambridge and one in Lynn.

How Class Room Is Arranged

"The classes should combine the most approved methods of pedagogy with every effort to eliminate eye strain. Much depends on the resourcefulness and the spirit of the teacher, as she must be able to adjust her methods of teaching to the individual need of each child under her care. The school room should be particularly well lighted without direct sunlight; the desks should be port-

able, so that the children can shift them to avoid too strong a light which might cause discomfort. There should be ample blackboard space as these children are encouraged to do their written exercises very largely on the blackboard. The paper used in ordinary grades that is, white paper ruled in blue lines, is always eliminated and in its place a large sheet of dull paper is substituted. Instead of using pen and ink the children are encouraged to use a soft large lead pencil similar to those used in kindergarten classes or by carpenters.

"Through the experience of practically every one who has been interested and really knows the work demanded of a teacher caring for a group of these children it is stated that ten children should be considered a proper unit for one teacher to handle. Boston has increased this number to twelve and in New Bedford where no child is included in this class who is doing work beyond the fifth grade, the teacher is handling twenty-two. This however, would not be possible if her class included the higher grades.

"Special attention is given to the handiwork of these children. Typewriting is considered advantageous to all children in the upper grades.

"Children who have been repeaters and a few who have been considered mentally backward have been able to do well in these classes. Although a group of ten or twelve materially increases the *per capita* cost of the children in this group, if, in the long run, it eliminates repeaters and removes the child who is hindering his class through demanding more time from his teacher than he is really entitled to in the ordinary group,

Arithmetic lesson in one of Boston's sight-saving classes.

such a class would surely be justified financially. On the other hand, the economic aspect of this class from the view of sight saving alone is a big item to be considered.

"By reaching the child of school age (up to seventeen years) much can be done toward check-

ing certain eye conditions and diseases which, if neglected, might result in great loss of eyesight, or even blindness, in adult life. As illustration, a child in one of our sight saving classes has high myopia and appeared to be nearly blind when we first discovered her. With corrective glasses her

Sight-saving class in Charlestown, Mass.

vision improved to about one-third of normal and, although the trouble is of a progressive nature, her vision has remained about the same for two years. The father is blind—cause, separation of the retina from neglected myopia. He had not obtained medical advice until his eyesight—all but a dim perception of light and shadow—had gone. We believe his child has been saved from a similar fate largely through the advantages of a sight saving class."

A brief description of one of the Cleveland classes will indicate the care that is taken to safeguard the remnant of vision that the pupil may possess. The school room has abundant light, but glare is eliminated by calcimining the walls in a neutral tone and finishing the desks and wood-work in a mat surface. Each pupil has a black-board attached to his desk.

Conserving the Pupil's Sight

The work is oral, written and manual. Oral arithmetic, history, geography, and language are taught in the regular class rooms. Written arithmetic and spelling are done on the pupil's black board. Textbooks are printed on heavy yellowish paper in thirty-six point clear-faced type. Touch typewriting is taught. In the manual training classes the work is carried on as far as possible without the use of the eyes. The girls receive lessons in cooking and serving, and sewing is taught according to the methods used in teaching the blind.

Cleveland employs a school oculist and only those recommended by him can be admitted to the

class. The teacher in charge receives definite advice from the eye specialist regarding the amount each child may be permitted to use his eyes. Re-examination at stated intervals determines whether the child is holding his own or not. Progressive decrease in vision causes transferral to classes for the blind. This provision for examination and reexamination of the eyes has been recognized as vitally important, not only by oculists but also by educators. Superintendent Dyer of Boston believes that such classes should not be established unless at the same time there are provided ophthalmologists to make periodical expert examinations of the children's eyes in order that the kind of training may be so adapted to the individual child as to improve rather than to injure the fraction of vision he may possess.

What percentage of school children have sight so defective that they cannot be educated in ordinary schools? This question can be answered only in communities where an accurate survey of the ocular status of the school children has been made. In 1916 a careful study conducted by the Massachusetts Commission for the Blind led to some definite conclusions. In eleven cities and towns the vision of 26,164 pupils was taken. Of this number 4.1 per cent had vision of 20/40 or less; 2.5 per cent were neither wearing glasses nor had been examined by experts. Of the two latter classes 0.28 per cent were recommended by specialists for transfer to sight saving classes. I quote from the tenth report, Massachusetts Commission for the Blind: "On the whole our results in

Recreation in one of Boston's sight-saving classes.

the towns which we know most thoroughly this year tend to confirm our last year's statement based on a study of cities that it is probably safe to say that not merely 0.12 per cent, but as many as 0.4 per cent of the whole school population of the state require teaching in sight saving classes. Another investigation of 40,259 school children in

three Massachusetts cities showed 840 possessed vision of 20/50 or less. An expert investigation of 456 children with defective sight (including those helpable by glasses) led to the conclusion that 68 (14.8 per cent) should be in special sight saving classes.

"The semisighted child is discouraged with always being behind his fellow students and develops a consequent carelessness, shiftlessness and lack of confidence. Later his lack of the fundamentals of education and the shiftless habit acquired in a desultory school course must inevitably handicap his industrial life." This statement from a report of the Massachusetts Commission for the Blind coincides with my own recent experience. As a member of a medical advisory board I have had occasion to examine a large number of young men with disqualifying ocular defects, high hyperopes and myopes, sufferers from corneal and retinal diseases, etc., and I have been struck with the large number of these men engaged in less remunerative occupations. Almost always there is the same tale—early abandonment of school because the work could not be done.

Not very rarely the child with defective vision is also mentally inadequate. The question then naturally arises: is or is not the mental deficiency dependent on the visual defect? The affirmative has been maintained by some ophthalmologists. I am old fashioned enough to agree with Guy C. Fernald, who says: "The relationship of mental and visual defectiveness is not one of cause and effect, generally, but one of association. A marked visual defect is a contributory cause in the inefficiency of an individual, but it is not *per se* a cause of mental enfeeblement, since feeble-mindedness is a congenital defect or is traceable almost without exception to some other accident. While the development of the young is retarded in some degree at least by any defect in any of the special senses, yet visual defectiveness is not a direct cause of mental defectiveness." Mrs. A. Everett, teacher under the London City Council, reports as a result of comparative mental tests on partial-sighted children in part time attendance in regular classes that 10 per cent were below, 10 per cent above, and 80 per cent were equal to normal children in the classes in which they worked. The idea of compensating sense development is erroneous. While certain psychologic tests are often in favor of the blind, they are retarded in others and defective vision in marked degree should always be regarded as a handicap to be overcome by special educational methods.

In the handling of special problems connected with the education of children variously handicapped, most of our cities are commendably pro-

gressive. They have established schools for the mentally defective; ungraded classes have been instituted for the borderline, backward, and restoration types of pupils. There are schools for deaf or nearly deaf children, and open air schools are doing wonders in the upbuilding of anaemic and pretubercular children. There are also special classes for truant and unruly boys. So far, there has been very little done toward providing for the needs of the semisighted. Society says, in effect, to these defectives: "You have chosen your handicap carelessly. If you had some other defect, I could educate you."

Ohio leads in this work with classes for the semisighted in seven cities: Alliance, Ashtabula, Cincinnati, Cleveland, Lorain, Mansfield, and Toledo. Massachusetts has provided special classes in Boston, Cambridge, Lynn, Worcester, and New Bedford; New York, in Buffalo and Rochester; and Michigan, in Detroit.

The cost of such special education varies with location, equipment, etc. It is the highest of any special educational work done in the public schools, but considerably less than the cost of education in institutions for the blind. This cost can be further reduced by placing such children as far as possible in classes with seeing children, which has the additional advantage of accustoming them to a normal school environment in competition with those with whom they will be thrown in later life. Such classes should be subsidized by the state in the amount they cost in excess of the cost of educating a child by ordinary methods. Another factor to be considered is that, although the *per capita* cost is greater, there are no "repeaters," and that complicated and expensive problem in the public schools is obviated. In order to secure the best results, the parent should have as complete an understanding as possible of the problem of his child from the standpoint of the school. Friendly visits should be encouraged, and the teacher or school nurse should be ever ready to enlighten the parent to the end that the latter may have a sympathetic appreciation of the child's handicap. The whole aim is to minimize eye strain during school life, to train the semi-sighted child to conserve his own vision, and to give such vocational training as will enable him to become self-supporting.

The vast program for the rehabilitation of our soldiers crippled by wounds received in defense of our country shows the people's will to re-establish in economic independence those who have been maimed. Shall the child handicapped by defective sight not be given that specialized education which will in later years fit him to become a happy and productive citizen?

REMINISCENCES OF A PRACTITIONER

The professional ethics of the general practitioners of England are the fertile soil out of which there will grow an enriched, highly socialized medical science in the future, according to an interpretation by Dr. James Pearse, a noted English physician, who has written a personal retrospective sketch for the *Lancet*. Dr. Pearse relates at length his intimate impressions and reminiscences of more than twenty years. It is such a sketch as almost every physician thinks he may some day write as a record of his professional work and life.

The isolation of the general practitioner in his work and studies, Dr. Pearse calls at once a beneficial source for engendering a wholesome spirit of independence in the individual, while acting also as an effective barrier to the physician's chances of keeping abreast of the progress in specialized branches of medical science.

The prime need of the general practitioner, he thinks, is an extension of the facilities for post-graduate study so that each locality will provide its group of physicians with means and centers through which they may extend their acquaintance with current contributions to scientific knowledge, and at the same time form closer relationships with their fellow physicians.

Of the difficulties of general practice, Dr. Pearse writes:

"A danger associated with the fullness of the practitioner's life is that which may always follow excessive concentration on one subject—namely, a failure of interest in other phases of life. It is illustrated by the fact that few general practitioners retire from practice; the majority die in harness. The reason, to a large extent, is that not many are able to lay aside the means to provide for later years; but a further reason is that work has been so absorbing that there has been too little opportunity for the cultivation of hobbies or outside interests, and thus without the interest of work life would be lacking in zest."

He suggests the devices and methods by which post-graduate studies may be carried on by the physician who has an established practice without interference with his everyday tasks. He says:

"When once a man has developed a busy practice the demands on his time are so continuous, periods of leisure are so scanty, that opportunity for study is but limited. However laudable intentions may be, attainment of necessity lags behind.

Postgraduate Work Too Restricted

"There are three directions in which it would appear that this requirement might to a certain extent be met.

"Facilities for such exist, but only a limited number of practitioners are able to avail themselves of these. Holidays from general practice are rare and refreshing, and no small degree of enthusiasm is needed to forego such for the sake of study. And to leave a practice for any lengthened period is both costly and hazardous.

"Some modifications of the present system seem worthy of consideration. The number of centers where post-graduate training has been developed is limited. The development of such work at other centers would be an advantage, especially if the work were so arranged as to be available to practitioners in the adjacent area without undue absence from practice. Many practitioners who would find it impossible to attend a prolonged session would make an effort to attend a short course—for example, a series on six or eight afternoons or evenings once a week; and in a specially adapted course much might be learned in that limited time.

"A further modification might be advisable as applicable for more rural areas where even the limited attendance above indicated would involve too long absence from home. There might be developed extension lectures in medicine, and a lecturer attend occasionally at a given center in the country for the enlightenment and encouragement of the rural practitioner. True, such lectures could not be attended by a large number, and would not be directly remunerative to the lecturer, but their value might be very great.

"Further, the hospitals might render very material assistance to the general practitioner by developing courses of clinical lectures at times adapted to his convenience. And especially would this be the case if use were made of hospitals not only in the recognized teaching centers, but also of those situated elsewhere."

Similar to the extension work which Dr. Pearse urges in lecture courses and hospital, he calls upon his fellow physicians to bring within easier access of the practitioners in every locality the specialist facilities and a knowledge of their requirements. On this aspect of the physician's world, he makes this comment:

Extension of Specialist Facilities

"An extension of specialist facilities, so that there might be more ready access for the average general practitioner, would be a great boon. Especially is this true as regards the practitioner in the country or the small country town. The city practitioner has facilities at hand, and may have access to them when he will and if he will. His more isolated colleague is by his isolation handicapped; he may send a patient to be x-rayed and have to be content with a photograph, which perhaps he does not understand; he may receive a detailed diagnosis of an obscure heart case, but know nothing of the technique involved; he may send a scraping of a chancre to a pathologist, but the spirochaete may be only a name *Exerto crede*.

"The continuous development of the general practitioner, which is so essential, is impossible without an extension of facilities. But here, again, the middle course is the safest. To spoonfeed the practitioner, to encourage him to depend too exclusively on the resources of others, would be disaster. Isolation or semi-isolation is not without its advantages; it develops a resourcefulness and self-reliance which in many an instance are of more avail than the most up-to-date knowledge."

Dr. Pearse finds good and bad points in the prevailing mode of presentation in medical literature. The main resource of learning and advancement for all practitioners must be in medical literature, he observes.

"The assistance which the practitioner seeks from books," he writes "is mainly in two directions—clinical instruction which will help him in his daily round, and instruction in new developments. As regards the former there has been much improvement in recent years. Time was when there were only ponderous tomes, weighted with unrequired details, which had to be laboriously sifted in order to obtain the essential knowledge. The practitioner does not require the elaborate text-book, but the graphic presentation of the essentials of diagnosis, prognosis, and treatment—the clinical portrait. It is on the clinical lecture of his student days, impressed by the personality of his teacher, that his knowledge of practical medicine is really based, and it is the continuance of such vivid type of teaching that he still desires. That such literature is more in evidence is of good omen, but there is still a tendency to dwell unduly on the rare."

Experience brings to the physician the recognition

of a secondary place that he fills in waiting on and assisting the efforts of nature," says Dr. Pearse. In terms of social units or community groups, he expresses this thought of the practitioner's service to mankind in a prophetic spirit, with a vision of betterment for the future. He voices a creed of optimism, saying:

"The general practitioner who moves amongst various sections of the community, practicing amongst the wealthy and the poor, amongst those well fed and those under-nourished, amongst the well-housed and the ill-housed, amongst the over-worked and those capable of leisure, be they rich or poor, knows that the incidence of sickness and of types of disease vary according to the surroundings and circumstances of his clientele. And experience justifies a reasoned optimism that with wider knowledge, a saner life, and a healthier environment the community will ultimately escape from many ills which now seem inevitable."

LAW FOR THE DOCTOR—THE PHYSICIAN'S LIABILITY FOR ACTS OF HIS PARTNER

BY LESLIE CHILDS, ATTORNEY AT LAW, INDIANAPOLIS, INDIANA*

The partnership relation, while pleasant and profitable at times, frequently carries with it an element of danger, because it is fundamental that one partner is liable for the acts of the other, if committed within the scope of the business.

In the professions, partnerships are met with, in proportion to the numbers engaged, perhaps more frequently than in the commercial world. Professional men presumably are slower to avail themselves of the advantage of a corporate name, which in their case also presents some difficulties and disadvantages, that are entitled to consideration.

This is particularly true of the medical profession; some jurisdictions questioning their right to incorporate, and, in addition their relationship with their clientele being of such a personal nature, that it is difficult of embodiment in a corporate name. Possibly in a great measure because of this, partnerships composed of physicians and surgeons are quite common; therefore, the question of partnership liability becomes, to them, one of great interest and importance.

There are a number of interesting cases in the books bearing on the question, but *Haase vs. Morton*, 138 Iowa 205, is probably as clear a case of partnership liability relative to a professional partnership as they contain. And it might also be termed a borderline case, and probably represents the limit to which the courts will go.

The facts were in substance as follows: William M. Morton and L. B. Morton were physicians engaged in the practice of their profession under the firm name of Morton and Morton. Dr. William M. Morton was called upon to attend the plaintiff professionally.

After an examination he determined on an operation, to which the plaintiff consented, and suggested that it could with greater safety be performed in a hospital. The plaintiff also consented to this and William M. Morton made the necessary arrangements for hospital accommodation.

In conducting the operation Dr. L. B. Morton administered the anaesthetic, and William M. Morton performed the operation; after which William M. Morton left the

operating room for the surgeon's dressing room, leaving L. B. Morton and the nurse to attend to the removal of the patient to her private room.

This private room was on the floor below the operating room, and the patient was placed on a rubber tired car and propelled to the elevator shaft. Arriving there they found the elevator down and the shaft open. Dr. L. B. Morton and the nurse, in attempting to summon the elevator man, left the car for a moment, and it rolled into the elevator shaft and fell, with the patient on it, a distance of about fifteen feet. For injuries alleged to have been received from this fall, suit was brought against Morton and Morton as a partnership.

The trial resulted in a judgment against both doctors in the lower court, and an appeal was taken to the supreme court. The defendant, William M. Morton, denied liability on the ground that whatever liability existed rested on the act of his partner, as he was not present at the time; also, that the removal of the patient to her private room was not within the scope of the business of the firm.

The supreme court in passing upon these contentions said in part:

"While it is shown that neither of the defendants owned or controlled the hospital, it does appear that they made all arrangements for plaintiff's stay there, and a jury would be justified in finding that the defendants as part of their employment undertook to care for plaintiff from the time she entered the hospital until she was ready for discharge therefrom. And while this might not ordinarily include the work of the hospital employee's the doctors might assume the duty of returning the patient to his room, and in such event each member of the firm would be the agent of the other in carrying on the work.

"It is fundamental that each partner is the agent of the firm while engaged in the prosecution of the partnership business, and that the firm is liable for the torts of each, if committed within the scope of the agency."

The court then affirmed the judgment, there being however one dissenting opinion.

But it must be remembered that to charge one physician with the acts of another the partnership relation must exist. The occupation of a common office will not make them partners; neither will the working together on a case as in consultation. And unless there are some very potent reasons for forming such a relationship it is a status that should be avoided.

MAKE INFLUENZA SURVEY IN U. S.

A statistical study of the incidence, chronology, and distribution of influenza during the epidemic of 1918 has been undertaken by the United States Public Health Service. The survey will include all states. Special studies will be made in representative localities to determine the incidence rate, type, duration, and fatality in relation to race, age, sex, and living conditions. The statistics of state health departments will be used to learn the chronology, sex, and age distribution of cases. Certain special groups or communities will be investigated, and an analysis made of reports available from foreign countries. Offices for the investigators have been established under the direction of W. H. Frost, surgeon, and Edgar Sydenstricker, statistician, who will be assisted by Prof. Raymond Pearl, Ph.D., of the Johns Hopkins University School of Hygiene and Public Health, as consultant. Their studies will include an inquiry into the methods adopted in various localities for dealing with the epidemic and for the prevention of the disease. The investigators will report on the preventive measures of other countries as part of their survey.

THE MONTH IN MEDICINE

Survey of Current Medical Literature with Editorial Comment

WALTER W. HAMBURGER, M. D., Editor

CARDIAC PROGNOSIS—ARBORIZATION BLOCK

CARDIAC prognosis is at once the first consideration of both patient and physician. The prognosis, moreover, concerns itself not so much as to whether the patient will recover from his affection but rather with the questions: Will he die from it? and when? Outside of the patient's own personal interest as to the approximate time of his death, his family, his business or professional associates, often vast political and financial interests may be deeply and intimately concerned.

Recent electrocardiographic studies throw some light on this absorbing problem. Robinson¹, in 1912, from electrocardiographic records of seven patients at the time of death from various causes found that fibrillation of the ventricles, similar to fibrillation of the auricles—auricular fibrillation—preceded briefly complete cardiac arrest in one and possibly two instances.

In 1917 Robinson² and Bredeck described a case of ventricular fibrillation in man with cardiac recovery.

Oppenheimer and Rothschild³ in the discussion of the electrocardiographic changes associated with myocardial involvement set forth the electrocardiographic findings of sixty-two cases of so-called intraventricular, bundle branch, or arborization block. This series presented the clinical pictures of cardiovascular renal disease, atherosclerosis, coronary artery disease, angina pectoris, myocarditis, syphilis, acute articular rheumatism, "grip," diabetes, gout, etc. As to the prognoses of these cases, they state as follows:

1. Robinson, G. Canby: A Study with the Electrocardiograph of the Mode of Death of the Human Heart. *Jour. Exper. Med.*, 1912, xvi, 291.

2. Robinson, G. Canby, and Bredeck, J. F.: Ventricular Fibrillation in Man with Recovery. *Arch. Int. Med.*, 1917, xx, 725.

3. Oppenheimer, Bernard S., and Rothschild, Marcus A.: Electrocardiographic Changes Associated with Myocardial Involvement, with Special Reference to Prognosis. *Jour. Am. Med. Assn.*, 1917, lxi, 429.

4. Robinson, G. Canby: The Relation of Changes in the Form of the Ventricular Complex of the Electrocardiogram to Functional Changes in the Heart. *Arch. Int. Med.*, 1916, xviii, 830.

5. Cohn, Alfred E.: Personal communication.

6. Willius, F. A.: Arborization Block. *Arch. Int. Med.*, 1919, xxiii, 4, 431.

"Special emphasis should be laid on the serious prognosis in patients showing electrocardiograms indicative of intraventricular block. Of the 58 showing arborization block, 22 are dead, 24 are alive (of these 4 are in a precarious condition, and 12 could not be traced). Of the patients whose fate is known, the mortality has been 48 per cent within two years. . . .

"There have been 22 other patients suffering from angina that have not shown these electrocardiographic changes; of these, only 1 is known to be dead, 17 are known to be alive and 16 of the seventeen are doing well or fairly well. . . .

"On physical examination two signs have been especially noted: (1) a muffled, poor or practically absent first heart sound, and (2) a gallop rhythm. One is often struck by the fact that the heart is hypertrophied but that the first sound, instead of being blowing, has a muffled quality."

Their final conclusion is interesting: "We venture to state that there is a definite clinical condition to be known as arborization block; that this condition can be diagnosed by the presence of a definite and permanent type of electrocardiogram; and that the condition has a very serious prognosis."

Robinson⁴ describes similar ventricular complexes—widening and notching of the R wave—but does not believe they are necessarily permanent. Cohn⁵ is of the same opinion.

Further recent confirmation of the importance of arborization block comes from the Mayo Clinic by Willius⁶ who states that "arborization block or impaired intraventricular condition is dependent on graphic records for its recognition. It is now generally accepted to indicate disease of the subendocardial myocardium and evidences serious functional cardiac disturbance. . . . The present study was undertaken to determine if possible the significance of this disordered mechanism with especial reference to life expectancy." Willius examined 138 patients with arborization block. His conclusions are as follows:

"(1) Arborization block is a grave disorder of the cardiac mechanism; it entails a large and early mortality (69.6 per cent) in an average of eight and one-half months.

"(2) Disorders responsible for the development of this condition were found to be in order of frequency: (1) infection, (2) degenerative processes, and (3) local nutritional disturbances.

"(3) The relative infrequency of edema was a striking observation.

"(4) The lack of definition and differentiation between the first and second sounds was constant."

Comment.—Comment on these contributions to cardiac prognosis is hardly necessary. We can anticipate with considerable certainty that the next few months will see further interesting studies on this new syndrome of arborization block. More light on the clinical findings is particularly desired, and every physician should so train himself in his examination of cardiac or suspected cardiac patients that new dependable data in history or examination of these patients may be elicited.

At present, the following findings seem to be significant: muffled, poor, or practically absent first heart sound; gallop rhythm; infrequency of edema; lack of definition and differentiation between the first and second sounds; electrocardiographically, widening, notching of the apex, and splintering of the ascending and descending links of the Q R S group, particularly of the R wave, have been established. With such findings the burden of stating a grave prognosis—48 to 69 per cent in two years—must be assumed. However, one cannot help feeling that this high mortality will eventually be decreased, and that as arborization block becomes more exactly known and its pathology and etiology more accurately studied, therapeutic measures for its control will likewise be found.

IMMUNITY IN ACUTE LOBAR PNEUMONIA

Mention of the fundamental work on serum immunity in infectious diseases is centered around the study of the crisis in acute lobar pneumonia. Before the days when pneumococci had been divided into groups distinguishable by their specific serum reactions a large part of the immunity work was unsatisfactory. It was difficult to demonstrate phagocytic or agglutinative properties of the serum as long as workers were unaware of the specificity of the antigen. Following the classical observation of Cole and Dochez, and the subsequent improvement in technical applications of older principles, Clough¹, and, independently, Lister were able to demonstrate definite

phagocytic and agglutinative activity in the serum of pneumonia patients after crisis when tested with the homologous organism; and when tested with heterologous strains, phagocytosis and agglutination occurred occasionally.

The present work deals with new studies on the same subject and practically the same method of technical procedure was employed as has been employed in earlier studies on the same subject. Again, the only difference has been in the employment of pneumococci of specific types. The strains of pneumococci used were usually those obtained from cases of pneumonia and were practically in no instance phagocytizable in fresh normal human serum under the conditions of the method employed; in fact, the organisms remained resistant to phagocytosis for at least several months of artificial cultivation.

The results of the test, both from the standpoint of phagocytosis and agglutination, are very striking. Of 33 cases in which the serum was obtained from pneumonia patients at or shortly after crisis or lysis and tested with the homologous strains of pneumococcus isolated from the same patient, 85 per cent showed definite phagocytic activity while 79 per cent gave definitely positive agglutination reactions. In contrast to these results, serum was obtained from 7 patients, who later died of the disease, with negative results in 6. In 18 of the 34 patients whose convalescent serum was actively phagocytic, tests made during the active stage of the disease were with three exceptions negative and these three exceptions were all obtained one day or less before the crisis. Clough concluded, therefore, that the serum of a pneumonia patient is negative during the acute stage of the disease and that phagocytic and agglutinative activity developed at or near the crisis, occasionally shortly before the crisis, but is often demonstrable only after recovery has definitely set in.

Comment.—Many workers in the field of pneumonia have felt from the clinical picture alone that at the time of crisis there must occur a pronounced change in the serum reaction of the patient. This work of Clough indicates that at this time there develops a new substance in the serum of the patient who is going to get well. This substance makes it possible for the serum to prepare for phagocytic digestion virulent pneumococci of the same type as the infecting organism in the individual case. Clough's results are so definite that there can be no question about the establishment of this fundamental fact.

¹ Clough, Paul W.: Phagocytosis and Agglutination in the Serum in Acute Lobar Pneumonia: The Specificity of these Reactions and the Regularity of Their Occurrence. Bull. of the Johns Hopkins Hospital, 1919, xxx, No. 310, p. 167.

OCCUPATION THERAPY AND TUBERCULOSIS

It is indeed a refreshing and important note to find a man who "from training and experience is influenced by consideration of mental factors" writing about the question of work in pulmonary tuberculosis. Much that has been written on this important subject has paid no attention to the fact that each tuberculous patient is an individual problem, that what is sauce for the goose is not sauce for the gander when discussing this large group of patients to whom society and medical science owes so much more than the group is obtaining. Statistics have been collected by the advocates of a complete rest cure proving that work of the tuberculous patient does not give as good results as does rest; and on the other hand men like Patterson, of Frimley, bring forward figures to prove just the opposite.

Dunton¹ has reviewed the more important contributions to the subject of occupational therapy in tuberculosis and calls especial attention from his review to the neglect in most previous discussions of the psychic factor of the individual patient. Even the absolute bed patient, who is placed on his back with strict injunctions not to get out of bed, is nevertheless given no opportunity to keep quiet because nothing is given him to use up his vital energy or allay his restlessness and worry. Although he is on his back, he may have a very active mind which, unless occupied, will produce considerable mental restlessness followed by more or less motor restlessness, and in this way the appearance of complete rest is not always synonymous with the actual obtaining of such rest.

Dunton, in association with Sloan of the Eudowood Sanitarium, has conceived the possibility of dividing the tuberculous into four groups:

1. Those who show signs of the disease with but few symptoms, who usually recover quickly, but who are difficult to impress with the necessity of sanatorium care.
2. Those showing signs and having symptoms sufficiently marked to make the patients feel that they are sick.
3. Those having extensive signs and symptoms, who have probably been treated for other ailments, the early diagnosis having been incorrect; who frequently have a temperature of 101°; who are desperately anxious to get well and therefore willing to cooperate.
4. The old chronicics who come to the sanatorium as a last resort for treatment, or to die.

They believe that mental content must be secured as a primary requisite for getting well. To secure mental content, each patient must be in-

dividually considered, first as to his physical condition, next his capabilities, and finally, his tastes or interests. When these three factors are sifted down, proper occupational therapy can be instituted with success and with the hope of rendering each patient not only healthier, but better able to carry on his life as a citizen. Not all patients can be given the benefit of occupational therapy, and, according to Dunton, excepting in rare instances it is doubtful if either one of his groups 3 or 4 would be benefited by bed occupation.

Comment.—It is to be particularly noted that the point of view expressed in this discussion differs from the generally expounded view that work of some sort is a necessary factor in the convalescent treatment of tuberculosis. As soon as the patient is put to bed when it is necessary to obtain complete rest, some form of occupation therapy suited to the individual needs of the patient can and should be instituted in a large number of such patients. It is only too true that individualization of the tuberculous patient has not been carried out as a necessary part of treatment. It is only too true that in some sanatoriums, for instance, patients are still fed calories instead of the food which satisfies them psychically as well as physically. It has long been recognized that certain elements of treatment in a sanatorium have had their value mainly in keeping the mind of the patient busy and yet certain sanatoriums still place all of their patients on the same routine. It is to be sincerely hoped that Dunton's suggestions will be carefully followed up by those interested in the treatment of the tuberculous patient.

INTRAVENOUS AND INTRASPINAL THERAPY IN MENINGITIS

BY JACOB MEYER, M.S., M.D., CHICAGO, ILL.

Recent experiences in the various military hospitals have led to the adoption of intravenous injections of antimeningococcic serum. While recognizing the value of such a method in true cases of meningococcemia, Amoss and Eberson² have raised the question as to the possibility and the degree of the passage of antibodies from the blood to the spinal fluid.

The attention of clinicians throughout the country has for some months been concerned chiefly with the observation of serum therapy in meningitis. The importance of the studies of Amoss and Eberson is apparent when it is remembered that recent experiences with meningitis indicate that it is a meningococcemia, and that

¹ Dunton, W. R.: Occupation Therapy and Tuberculosis, Med. Rec., 1919, xcv, No. 23, p. 941.

² Amoss, H. L., and Eberson, F.: Passage of Meningococcic Agglutinins from Blood to Spinal Fluid of Monkeys, Jour. Exper. Med., 1919, xxix, 597.

cases in which the spinal fluid shows no evidence of inflammatory changes are said to have developed meningitis when intravenous therapy was delayed.

Flexner showed that under normal conditions antibodies do not pass from the blood into the spinal fluid but, where the permeability is increased by inflammation, passage of antibodies may take place to some degree. The present investigators find similar results with respect to the agglutinins for the meningococcus. They find that normal monkeys which have received intravenous injection of antimeningococcus serum show no agglutinins in the spinal fluid, but when the meninges are inflamed agglutinins are able to pass from the blood to the spinal fluid. Assuming then that in cases of meningitis in man the meninges are inflamed, it may be reasoned that intravenous administration of serum would exert a protective action on meninges which were not already infected.

On the other hand, the question has been asked by Herrick, as to whether the intraspinal injection of serum does not favor the localization of meningococci from the blood stream in the meninges. As has been remarked, cases have been observed which showed no inflammatory changes in the meninges, as determined by studies of the spinal fluid, but with severe symptoms of infection in which meningococci were cultured from the circulatory blood. It is claimed that the production of an aseptic meningitis by intraspinal injections of antimeningococcal serum in such cases would favor the localization of the meningococcus in the meninges. Amoss and Eberson¹, however, find that in monkeys and rabbits the meningococcus cannot be made to pass from the circulating blood to the aseptically inflamed meninges. Their experiments do not lend support to the view that the intraspinal injections of antimeningococcal serum early in the course of invasion of meningococcus in man and even at a later period at which the meninges do not yet show evidences of inflammation favors its diversion from the blood into the meninges.

These authors are of the opinion that the increased permeability of the meninges and choroid plexus caused by the intraspinal injection of antimeningococcus serum would be more than offset the immunity principles introduced into the subarachnoid space along with serum.

Serum administered by the intraspinal method soon escapes into the blood, and these investigators have shown that the agglutinins dis-

appear from the spinal fluid at the end of twelve hours and appear in the blood as early as the fourth hour. On the other hand, after intravenous injections, when the meninges are inflamed, agglutinins appear in the spinal fluid in thirteen hours and remain in low concentration in the blood at twenty-five hours. After combined intraspinal and intravenous injection the agglutinins remain in higher concentration in the spinal fluid for a longer time than by either the intraspinal or intravenous method alone. These experiments emphasize the advantages of the combined method of serum therapy.

The intravenous administration of serum introduces a great quantity of antibodies into the circulation and thus the meningococcemia is more readily combatted. At the same time, antibody passes to the meninges and may act prophylactically in protecting against the production of a meningitis, or may act on the already inflamed and infected subarachnoid space; but it must be remembered that the quantity of antibodies which are thus transferred is probably very small, and that passage is delayed. The intraspinal administration is therefore to be advocated in addition to the intravenous injections as it furnishes a greater quantity of antibodies, and not only insures protection against infection but is much more efficient in combatting an existing meningitis.

Dr. Persons with Red Cross League

W. Frank Persons of New York City, formerly director general of civilian relief at National headquarters of the Red Cross in Washington, has been appointed director of development of the League of Red Cross Societies by Lieut. Gen. Sir David Henderson, director general.

FAULTY DIET BLAMED FOR PELLAGRA

A direct relation exists between family income, diet, and the prevalence of pellagra, in certain cotton-mill districts of the South, according to the conclusions presented by the United States Public Health Service as the result of a survey carried on among 747 families, living in seven localities of South Carolina, during a period of two years. These families were classified in four groups, and a close study made of the quality of the diet, the relative frequency of pellagra in the separate groups, and the sickness rate, with relation to the income. A deficiency in the supply of the animal protein foods was considered the chief cause of the disease in a majority of cases. The idea that a condition of general debility is a factor in the contraction of pellagra is said to be erroneous, due to the fact that the sickness rate and the number of cases of pellagra in the same dietary groups are entirely out of proportion, and because such a conclusion is not borne out by comparison with groups of non-mill working groups. The survey states: "The pellagra-producing dietary fault is the result of some one or, more probably, of a combination of two or more of the following factors: (1) a physiologically defective protein supply; (2) a low or inadequate supply of fat-soluble vitamin; (3) a low or inadequate supply of water-soluble vitamin, and (4) a defective mineral supply."

DIABETES AMONG JEWS—ITS CAUSE AND PREVENTION

BY ALBERT A. EPSTEIN, M.D., NEW YORK CITY*

THE purpose of modern medicine is prevention, and the best means of accomplishing this is through education. Open discussion of the subject of diabetes among Jews is peculiarly fitting and well considered because the problems which it entails are sociological as well as medical. The modern method of treating diabetes is mainly educational. It consists chiefly in guiding the patients in the mode of living suitable to their condition. Undoubtedly much in the way of prevention can also be accomplished by timely instruction in the conditions which lead to the development of this malady.

Sugar is one of the most important elements of nutrition. It is present in the blood and tissue fluids of every living being in the form of glucose or grape-sugar. Whatever the form of starch or sugar consumed, it is converted within the body into glucose. Its assimilation by the body tissues is essential to the continuation of the normal life-processes. Failure on the part of the body to utilize sugar leads to its accumulation in the blood and its elimination by the kidneys. The loss of this nutriment in the manner described causes a variety of morbid conditions.

Non-Utilization of Sugar in Diabetes

The chain of events which results from the non-utilization of sugar in the body constitutes what is known as diabetes mellitus. It matters little how much sugar or starch is consumed, sooner or later this nutriment is eliminated by the kidneys in part or all, as glucose. Its utilization cannot be promoted by increasing the consumption of such food stuffs; in fact, the greater the amount of starch or sugar ingested the worse the condition becomes. Also, other food stuffs are capable of increasing the production of sugar in the body and interfering with its utilization, so that improper and excessive use of sugarless and non-starchy food-stuffs may also aggravate the condition and augment the excretion of sugar in the urine.

Diabetes mellitus is a nutritional disorder, believed to be due to a functional disturbance of a certain organ known as the pancreas. The cardinal symptom of the disease is the passage of sugar in the urine. It is characterized usually by excessive hunger, thirst, increased frequency in urination, and, too, by the loss of flesh. Many

other symptoms frequently occur which need not be stated here. However, cases are often encountered in which many or all of the symptoms mentioned may be lacking and the condition may go unrecognized for a considerable time.

It is generally stated that this malady is more prevalent among the Jews, some authors contending that it is from two to six times as frequent among them as it is in the non-Jewish population¹.

In the discussion of this particular phase of the subject certain suggestions may be of aid in understanding the conditions which predispose to this disease, and the ways to meet them. It is a pleasant yet difficult task. Its burden arises from the fact that science has not yet revealed the specific cause of the trouble. Modern knowledge, gleaned chiefly from observation of the disease in human beings and from animal experimentation, has taught much concerning it, but we are still far from the goal. Unlike many other morbid states, the immediate cause of this disease is unknown. From the nature of things, therefore, many of the points which we must consider in the discussion of our subject are necessarily conjectural.

Radical Predilection for Diabetes

Is diabetes more prevalent amongst the Jews? If so, why? The Jews have long ago designated themselves as the "chosen" people and for that reason or some other have from time immemorial been regarded, by other races especially, as being uncommonly prone to some diseases and particularly free from others. But diabetes is an old disease. Definite mention of most of its cardinal symptoms is found in the literature of the Chinese of some six centuries B.C. Compared to other contemporary literatures, the Bible and the Talmud are rich in the discussion of medical subjects, yet no mention is made of any of the symptoms of diabetes. Biblical medicine states that the Jews of those days suffered frequently from boils or carbuncles.² It is possible that many such cases had diabetes, but that is a mere supposition. Another condition which is spoken of in the Talmud is Boulimia³, a disease that is characterized by extraordinary, practically un-

*Read before the National Conference of Jewish Charities, Atlantic City, May 30, 1919.

¹ The Jewish Encyclopedia, p. 553.

² Bergel, Joseph: Die Medizin der Talmudisten, p. 45.

³ Bergel, Joseph: Idem, p. 36.

satisfiable hunger. It is possible that some cases of diabetes may have been confused with this disease although in diabetes the hunger is by no means so extreme.

The fact that mention of diabetes is made in the ancient Chinese literature and none whatever in the early history of the Jews is not of mere passing interest. A disease which as a rule is so striking as diabetes in its manifestations, and so distressing to those who suffer from it, could not have escaped the attention of the Hebrew sages. The absence of any allusion to it suggests rather that the disease was either non-existent among them or, what is more likely, one from which they suffered but little.

Diabetes a Constitutional Disease

Diabetes is a constitutional disease and hence it has been assumed that differences in race, food, and manner of living cause differences in the occurrence and the severity of the disease. The literature on the subject is replete with examples and this assumption is supported both by analogy and by direct observation. Thus gout, which is also a constitutional disorder, is common among the Europeans and Americans, but very rare amongst the Japanese and is seldom, if ever, severe or fatal⁴.

That the Jew is peculiarly predisposed to diabetes is a matter of daily precept and common knowledge. From the ethnological standpoint the Jews are regarded as the best example of a people who have retained racial purity. The close adherence of the Jews to their religious tenets as well as the peculiar social and political position which the Jews until very recent times have occupied amongst other peoples has served to give them a state of isolation which has been conducive toward making them more homogenous as a people, and their mode of living uniform in character. History would seem to show that in ancient times the Jewish race was relatively if not entirely free from diabetes.

What circumstance then has been responsible for the remarkable change in this people to render them exceptionally prone to it now? One of two deductions is quite in place: either the mode of living of the Jews in the past few centuries has been so totally different from that of other peoples as to produce a profound and indelible impression upon their physical being such as to be transmitted from generation to generation; or the data upon which the current view concerning the prevalence of diabetes amongst the Jews is based are insufficient and erroneous. Both views perhaps have a share in the origin of the prevailing opinion.

Let us examine briefly what is generally known and believed of the incidence of diabetes among the different peoples and in different localities; and, too, the conditions which apparently predispose to it.

More Frequent Among Jews

The testimony of many physicians who have had a large experience with this disease goes to show that it seems from two to six times as frequent among the Jews as it does among the people around them. Some German physicians have dubbed diabetes, "die Judenkrankheit" or Jewish disease. Reliable statistical evidence as to its excessive prevalence among the Jews is, however, not very abundant and it is equally difficult from existing data to estimate its extent among people of other creeds.

It is reputed to be extremely common among the educated classes of the natives of India and Ceylon, but almost unknown amongst the negroes in Africa.⁵ On the other hand, many cases have been observed in the colored population of the United States. This tends to show that the alleged immunity of the negroes in Africa is by no means absolute or due to ethnic or racial causes. In Italy, too, the disease is quite common among the people, more so in the South than in the North. The differences in prevalence of the disease in two sections of the same country has not been definitely explained. There is abundant evidence that the Jews in Germany are very subject to the disease. In Hungary, also, their mortality from this disease has been excessive.⁶

Comparative Statistics

A few figures are indispensable as relating to its incidence. Auerbach states that of 487 deaths reported in Budapest as due to diabetes during 1902-1907, 238, or more than one-half, occurred in Jews, although they constituted less than one-fourth of the population.⁷ In Frankfurt, Wallach found that the number of Jews who died from diabetes during 1872-1890 was proportionately six times as large as the number of Christians who died from the same cause.⁸ In Prussia, Singer finds that the mortality was six and one-half times larger among the Jews than among the general population and in proportion to the total mortality it was even nine times more frequent among the Jews. It would seem from this evidence that the Jews are more commonly affected. On the other hand, See⁹ observed that

diabetes in France is no more common among the Jews than among Gentiles.

Morrison¹⁰ records 1,775 deaths from diabetes in Boston between 1895 and 1913. Among Jews the ratio of deaths from diabetes to the total number is 18 per 1,000 in contrast to 7 per 1,000 among non-Jews. In other words, in that vicinity diabetes is nearly two and one-half times as common among Jews. In New York City, also, it has been found that the Jews apparently suffer from this disease more often than others. Rudisch¹¹ has investigated the morbidity from diabetes from the records of Mount Sinai Hospital of New York City and compared it with that of non-Jewish institutions. He comes to the conclusion that it is nearly three times as prevalent among Jews as among Christians. Also, he adds that while the total number of patients admitted to Mount Sinai Hospital is three times as great as the number of patients of German origin, the striking feature is that of the diabetic patients those of German origin are six to one to those who are Russian. He ascribes the disproportion to the difference in social status. The conclusion is questionable and will be referred to again.

This was so in 1899. For purposes of this presentation the records since that date have been reviewed and conditions seem to have changed considerably. The accompanying chart (Table I) is taken at random from the statistics of the hospital and shows the marked differences in the number of diabetic patients of different nativity who enter the hospital. The predominance of diabetic patients who are Russians is in marked contrast to the figures which Rudisch obtained in a similar survey twenty years ago.

The statistics upon which our opinions of the relative frequency of diabetes in Jews and others are based cannot as yet be regarded as final. It is obvious that the discrepancy between the figures of Rudisch of 1899 and those presented herewith is only apparent, and is due to a difference in the character of the population from which the hospital draws its patients from time to time. The facts presented demonstrate what little validity statistics possess as gathered by individuals from their limited experience or from circumscribed sources. It is a suggestive commentary on the values of conclusions reached concerning the incidence of this or that disease from insufficient or fragmentary evidence. One can prove anything by statistics not sufficiently analyzed.

Objection might be raised to this criticism of medical or vital statistics, and it may be regarded as irrelevant to the question of incidence of diabetes in Jews, but judging from the trend of more

recent observations it is likely that the belief concerning the greater prevalence of diabetes in Jews may be no more than a tradition without foundation in fact. One can see how fallacious it would be to concede from statistics tabulated herewith that Russian Jews are more prone to diabetes than German Jews or those from any other quarter. Yet a conclusion of like character concerning the German Jews was reached by an authority on the subject on evidence equally faulty. What is true of this is also true in a large measure of the broader claim concerning the incidence of diabetes in Jews and non-Jews.

The statistics of death rates which are available are not comprehensive enough to warrant definite deduction. The records on the morbidity or incidence of the disease all agree that Jews supply an extremely large quota of patients suffering from diabetes but the figures available on this matter cannot be accepted without reservation, particularly those from foreign sources. They are mostly taken from patients treated in health resorts and sanatoriums, where well-to-do patients from all parts of the world are wont to flock for relief. While of other Europeans mostly the rich and prosperous come to these places, as Fishberg¹² rightly states, it is not so with the Jews. Besides the prosperous there come also many Jewish patients who are poor, all seeking a cure from the hands of some famous physician. It is clear that they swell the proportion of the Jewish diabetics on the books of the physicians at these resorts.

Here in America statistics on relative death rates from this disease are still too small to be of

¹² Fishberg, J.: The Jews, a Study of Race and Environment, p. 300.

from diabetes who are under observation and treatment. But does this constitute reliable evidence that diabetes is more prevalent among Jews and warrant the broad generalization that it is due to racial proclivities? The explanation is to be sought in several circumstances, the first of which is a difference in temperamental characteristics. There is an apt saying in German which cannot be suitably translated, and I will beg your indulgence for quoting it in the original language; "Wenn der Jud Durst hat, lässt er sich auf Zucker untersuchen, wenn der Christ Durst hat, trinkt er." This epitomizes the marked contrast between the attitude of the Jew and Gentile toward disease in general. The Jew has a horror of disease and of death and is more apt to magnify than minimize his ailments. He seeks medical advice on the slightest provocation. He is anxious about himself, demands an explanation for his symptoms, and often is not content with one opinion. The Gentile on the other hand discredits his maladies, and goes to the doctor only when forced to do so by great suffering or disability. He discounts the signs of disease and often interprets symptoms according to his own imperfect understanding. He, therefore, seeks relief for his symptoms far more frequently from nostrum vendors and spiritual healers than the Jew.

The effect of two such opposite tendencies on medical statistics is quite obvious. The Jews apply for medical advice in relatively greater numbers. A realization of this difference between the Jew and others affords an explanation for the fact that Jews furnish a relatively larger quota of diabetic patients.

Factors Contributing to Diabetes

There are other causes of a more serious kind which contribute to the discrepancy. One of the great dangers of diabetes is its insidious character. There are numerous cases of diabetes which present no obvious symptoms. Persons so affected do not become aware of their afflictions until the malady is discovered by accident, for example, when a physician is consulted for some ailment which may be in no way connected with diabetes, or when life insurance is applied for. Under such circumstances the condition is discovered only by examination of the urine. When that is not done the malady goes undetected.

Another circumstance which undoubtedly contributes to the alleged disproportion in the incidence of diabetes among Jews and non-Jews is the fact that the Jews are and for many years past have been preëminently city dwellers. As such they have always had ready access to advanced medical opinion. It is generally claimed

that city dwellers are more prone to diabetes than the inhabitants of rural districts but that difference may be due merely to a difference in the mode of living, or it may be that a difference in medical standards and medical methods in the city as compared to those of the country has a share in causing a difference in the statistics? The latter view seems probable. This argument applies with equal force to the belief that there is a difference in the incidence of the disease among different strata of the same people.

For example, it is stated in reference to the inhabitants of Ceylon that the disease is more common among the upper classes. Much has been made of this point in discussions on the subject. It requires no great stretch of imagination to see that the upper classes are more likely to seek medical advice when suffering from any ailment. Until recently hospitals and dispensaries were not in great favor with any class of people and competent private medical advice was a luxury, resorted to only when unavoidable.

Recent Increase in Diabetes

It is known that the number of reported cases of diabetes has recently increased tremendously among all classes. Joslin¹³ states that "if diabetes should continue to increase in the next thirty years at the same rate as statistics show it has increased in the past thirty years, it would rival tuberculosis as a cause of death, and if this rate progressed for another generation diabetes would be responsible for almost the entire mortality of the world. Such a rapid increase is evidence in itself that a fallacy exists somewhere in the statistics." Convincing proof exists that the rise is not due to increase in the incidence of diabetes, but to a greater frequency in the recognition of the disease and the consequent improvement in the vital statistics on that point.

The fact that a disease is not recognized is not proof that it does not exist. The reputed prevalence of the disease among Jews is to be ascribed in large measure to the fact that they are prone to seek competent medical advice for their complaints. This view is further supported by the fact that Jews appear to tolerate the malady better than other people. Thus diabetes is a condition to which the Jew is believed to be unduly susceptible, and at the same time to be very tolerant of it which is paradoxical to say the least.

Specific Cause Unknown

In discussing the causation of diabetes, it must be remembered that some fundamental disturbance of nutrition is at fault, the true nature of

¹³ Joslin, E. P.: Treatment of Diabetes, 1917.

which is not yet known; but some factors are recognized as being provocative of the disease. Only those need be mentioned which have a bearing on racial characteristics. They are: (1) heredity, (2) obesity, (3) dietary excess, (4) strenuous life, and (5) nervous element.

Like some other diseases of obscure or unknown causation diabetes has been and still is attributed to a peculiar diathesis or proclivity of the persons affected. As our knowledge improves it may be found that it is not any racial proclivity which renders the Jews especially prone to diabetes. Certain habits of life, diet, occupation, and social environment may all react in a deleterious manner upon individuals of any race or creed who are endowed with a labile nervous system and defective constitution so as to disturb the nutrition. This is true of most nutritional disorders.

Heredity and Diabetes

On the assumption that diabetes is more common among Jews than other people various reasons have been given to account for this prevalence. Chief of these is the history of heredity. If the tendency to diabetes were a racial characteristic of the Jew, heredity would naturally be an important factor. The Jews marry exclusively among themselves and even close relationship is for them no barrier to marriage. As inbreeding is known to accentuate physical and other defects, it is reasonable to suppose that the influence of heredity should be greatest among the Jews. At first glance of the statistics which are available on this point it would appear to be true. Joslin¹⁴ finds among a little over a hundred Jewish patients that 27 per cent showed the presence of diabetes in parent or other members of the same family; whereas, out of the total number of his diabetic patients, numbering 1,187, only 21 per cent showed a similar tendency. On purely theoretical grounds a larger disproportion would be expected between the two sets of figures. It is obvious that the number of cases, particularly his Jewish patients, is insufficient for a definite conclusion on this point; yet Joslin's series represents the largest number of diabetic cases in the literature observed by any one man. Moreover, as Joslin himself states, "it is easy to exaggerate the importance of heredity, for diabetic patients naturally would be more liable to know of the presence of diabetes in the members of their families than would patients who did not have diabetes." At any rate, far better evidence of the predominance of the hereditary factor among the Jews than that which we possess is required in order to prove that racial proclivities play the part commonly assigned to them.

No great experience in diabetes is needed to discover the close association of obesity or stoutness with that disease. The presence of excessive fat or its antecedent history is encountered in a large percentage of the cases which come under observation and treatment. Joslin¹⁵ places the concurrence of obesity and diabetes at 40 per cent of the cases. My experience would seem to indicate that the two conditions are associated even more frequently, principally because of a larger proportion of Jewish patients in my practice. The Jews are commonly obese. They interpret fat as a sign of good health, but it is a serious business to get fat. Of 308 applicants for life insurance rejected for obesity, Romanelli reports 21 per cent as having sugar in the urine. Particularly serious is it for an individual of slight stature to put on weight which would be excessive even for a large frame. Authoritative vital statistics show that the prospect of life of individuals of a given age who are obese is far below that of individuals who are normal or somewhat below normal in weight for their height and stature.

Closely associated with obesity as a predisposing factor in diabetes is the question of dietary excesses. It is an erroneous assumption that the consumption of carbohydrates, *i. e.*, starchy food in large amounts, is conducive to the development of diabetes. It is the excess of food rather than preponderance of carbohydrates which does the harm. Indeed, it seems that a high percentage of starchy food in the diet does not predispose that way at all as is illustrated by the fact, previously mentioned, that diabetes in the Japanese is not very common, nor even very severe. That is so provided the amount of food consumed is not in excess of the needs of the body.

In respect to food it might be said without fear of gainsay the Jew is over indulgent. The high proportion of stout people among them is in itself good proof that they consume more food than is warranted by the body requirements, for the physical habits of the Jew are usually such as to make the natural food requirement rather low. His occupations are sedentary and he rarely selects pursuits which require the expenditure of great physical effort. In sport and exercise he indulges but little, and that only on rare occasions.

A poor musculature usually accompanies obesity. A poor musculature also results from physical inactivity and lack of exercise. One-half of the sugar in the body is stored in the muscles and a large part of it is used by them. Therefore it is not strange that fat people so often develop diabetes.

¹⁴ Joslin, E. P.: Treatment of Diabetes. 1917.
¹⁵ Joslin, E. P.: *Idem.*

A strenuous life has been considered by most authorities as of importance in the development of diabetes. That this is so cannot be doubted. One very frequently sees the development of diabetes in persons, particularly young persons, who exert great effort in the discharge of their duties or in the pursuit of personal ambitions. This applies equally to individuals of all races and creeds, but especially so to the Jew, for no race of people is more ambitious, or more eager to assert themselves individually than the Jew. He is not fond of cooperation or organization. He prefers to shift for himself and bear all the burdens on his own shoulders. He makes his life strenuous almost by preference and enters the struggle where it is most intense—namely, in the city. The Jew is preeminently a city dweller, partly through force of circumstances which surrounded his past, particularly since the beginning of the Christian era. His mental make-up is the result of such environment.

Of the known causes of diabetes, shock, fear, or intense emotional distress holds first place. It is obvious that nervous individuals would suffer the most under great stress. This is well illustrated by recent tests on young individuals undergoing severe class room examinations, a large number showing the presence of sugar in the urine. There is good authority for the statement that sugar in the urine is found more and more frequently in young individuals undergoing physical examination for life insurance. Nerve instability is often associated with the presence of sugar in the urine, an observation encountered with ever increasing frequency in insane asylums.

The occasional presence of sugar in the urine of individuals when suffering from great emotional or psychic stress is not proof of diabetes; it merely indicates that in predisposed individuals nerve irritation is capable of exciting the elimination of sugar through the kidneys. Whether such accidents finally terminate in a true diabetes cannot be definitely stated, but it is reasonable to suppose that when the nerve irritation is sufficiently serious, or the shock sufficiently prolonged, a true diabetes may develop. Many of our histories trace the time of onset of the symptoms of diabetes to some great emotion.

Cumulative Psychic Disturbance

That the Jews are an extremely high-strung and nervous people cannot be denied. The frequent occurrence of neuroses and psychic disorders of all kinds among them is well recognized, but that this fact is due wholly to a racial characteristic cannot be admitted. It is far more likely that it is the product of sad experience.

History supplies enough facts to account fully for the instability of their nervous system. The conditions under which the Jews have lived for many centuries, particularly during the middle ages, have been such as would shatter the most resistant nervous system. We know what baneful influences suffering and misfortune can exercise on the mental and physical being of man. The recent war affords many sad examples of that. How much more profound must that influence be on a people who for very many generations, year in and year out, from the cradle to the grave, have endured oppression, privation, and every possible mental distress! The emancipation of the Jew, which is only of recent date and not yet complete, could not come about without some effect on a nervous system already unstable. The transition from the state of isolation and oppression of the past to the freedom of the present has been too sudden not to react like a shock. With restrictions removed their emotions have no bounds. They laugh and weep aloud. They have new desires and new ambitions. Always restless and never content, they strive and thrive in the face of many difficulties but at the expense of their physical being.

These circumstances have produced many of the factors which predispose the Jew to diabetes. One cannot undo in a brief space of time the effects of centuries. The characteristics which the Jew exhibits are acquired not racial, and the marvel is that he does not suffer from diabetes more frequently.

Education Provides Relief

Fortunately, the Jew is interested in his welfare and by virtue of this fact can be readily taught the means by which he can preserve his health. He must be made to understand that his predisposition to diabetes is not a racial stigma from which there is no escape. He must be informed that he possesses many attributes which render him more vulnerable than other people, but that he can overcome them by properly directed effort.

For the reasons presented the Jews possess many attributes that predispose to diabetes and on purely theoretical grounds should contribute a larger quota of individuals suffering from this malady. The available data would seem to confirm this supposition but this statistical evidence is fragmentary, conflicting, and unconvincing.

For reasons of prophylaxis or prevention it is safer to assume that they actually do fall prey to this disease more often than non-Jews, but it must be clearly understood that this predilection is through circumstance, temperament, and

choice of habits—all controllable conditions—rather than through any racial proclivity.

Moderation in the mode of living, mental poise, and physical self discipline are attributes which the Jew must develop in order to lessen any existing tendency to nervous instability and to nutritional disorders.

The practice of undergoing a physical examination once or twice a year at some public institution or at the hands of a private physician will aid in discovering diabetes in its earliest stages, when it is most amenable to treatment. That is the best form of prophylaxis or preventative medicine and the most practical method of avoiding and controlling diabetes in all races.

MAKING REHABILITATION OF DISABLED A PERMANENT PROGRAM

Training centers for the disabled of industry and physiotherapy departments in all hospitals that serve large communities are projects which Col. Frank Billings, M.C., United States Army, wishes to see carried out in the near future as a means of giving permanence to the methods and program of the army for the rehabilitation of disabled men, over which he has exercised supervision in military and government hospitals.

The adaptation of vocational studies and physiotherapy in the military hospitals has done much to improve the morale and maintain discipline, and has been effective in preventing hospitalization, according to Colonel Billings. He believes that similar good results may be expected from the application of the same methods in the rehabilitation of the disabled of industry.

The problems, difficulties, methods, and results of the government's rehabilitation program for disabled soldiers are set forth by Colonel Billings in an article on "Rehabilitation of the Disabled," appearing in *The Journal of the American Medical Association*, issue of May 24, 1919. The paper was prepared as an address before the Institute of Medicine, of Chicago. Part I discusses the rehabilitation of the war's disabled, and Part II relates to rehabilitation of the disabled of the industrial army.

The contact which hundreds of American medical officers, medical enlisted personnel, and nurses have experienced in the practices of modern military medicine and surgery in the field and in the convalescent hospitals; their first-hand knowledge of preventive methods as employed in the armies of the United States and the Allies in the control and prevention of communicable diseases, injuries and infection of wounds, and acquaintance with the manner of dealing with difficult conditions of camp sanitation and waste disposal, mean that the medical personnel of the army will return to civilian life prepared to give the benefit of their combined knowledge and experience to the improvement of health standards in civilian life and in the industries.

Their training and their experience in modern military medicine and surgery represents a knowledge of standards and methods that are the outgrowth of the aggregate experience of the medical departments of the armies of the Allies and the United States, including cooperative research and clinical conferences.

The army medical officers were successful in reducing to relatively small proportions the occurrence of gangrene and other serious types of infection in open wounds, with

a consequent reduction of disabilities through the loss of legs or arms.

The successful application of lung surgery at evacuation hospitals and the saving of life that resulted, Colonel Billings declares to be one of the remarkable events of the last year of the war.

The application of knowledge gained by military clinical experience in the treatment of "shell shock" cases, saved thousands of men from going home to a life marred by some type of mental and nervous disability, and probable dependency. The payment of pensions to this class of invalids was avoided, and a loss was turned into a gain, by sending the patients back to lives of usefulness in industry.

The Surgeon General of the Army has stated that soldiers injured in combat were cared for with such success that 85.5 per cent were restored to duty and returned to combat service, and 5 per cent were made fit for special or limited duty in noncombatant service. In other wars the proportion of men permanently disabled and killed, as compared with the injured who were returned to duty, has been the reverse of the percentages cited.

Among the remaining 10 per cent were the blind, the deaf, patients with amputation of limbs, serious maxillo-facial injury, serious peripheral nerve injury, empyema from trauma of lung or pleura, and other surgical conditions. For the victims the educational and vocational branches of the government rehabilitation enterprise have made special provision for physical reconstruction.

The fact that only 10 per cent of the disabled could not be returned to duty is due to the efficiency of the army methods in the application of curative work, physiotherapy, graduated exercises and military drill, and carefully planned training and play. A large number of the 10 per cent who were unfit for further military duty will be returned to civil life in good health and will be prepared to become self-supporting through the vocational training they are now receiving.

That equally efficient application of restorative methods may be adopted by industry, and should be applied, sums up the study which Colonel Billings presents on the subject. He states the proposition emphatically, in words as follows:

"The application of mental and physical rehabilitation to sick and disabled soldiers by practically all of the nations engaged in the war has proved so successful and beneficial that it imperatively demands the application of like measures for the benefit of the disabled of the army or of the industrial world."

The Federal Government and the states should standardize the measures for the prevention of injuries, accidents, and disease, and should enact legislation making compulsory the application of these standards, Colonel Billings declares.

"Many industrial corporations," he says, "have already learned the value of the application of measures of disease and injury prevention. Better sanitary conditions have been established and safety devices adopted which have been of the greatest value to employer and employee. These measures of safety provision should be standardized and universally applied, under a law of compulsion."

The hospitals would provide the starting point of such a program of rehabilitation by the establishment of departments of physiotherapy, by maintaining departments properly equipped, by standardizing, and by assisting where possible in the vocational training of the disabled. In the opinion of Colonel Billings, the field of vocational reconstruction should be reserved to the training centers which he proposes.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

SOCIAL WORK. Essays on the Meeting-Ground of Doctor and Social Worker. By Richard C. Cabot, M.D.*

The profession of the social worker did not develop from the exalted motives of the charitably inclined who desired to help those less favorably situated than themselves, but was the outgrowth of the needs felt in every avenue of effort for public betterment. The educator traced his failures to cases of malnutrition, of dullness due to conditions beyond the pale of the schoolroom which must be understood if his work is to be effectual; the judge of the juvenile court found he could not pass judgment on a case without details of the circumstances and temptations preceding the offense; dispensary workers found drugs of no avail unless food and sanitary conditions were right at home; and physicians could not even diagnose their cases unless the social and industrial as well as the clinical history was taken.

For the time is past when physical ills are regarded as mere physical disorders to be remedied by a pill or a powder; they are no longer regarded as isolated "happenings" but as the logical outcome of combined physical, social and economic indiscretions which must be diagnosed and corrected by hygienic methods before a hope of cure can be entertained.

The volunteer charity worker first attempted to fill the need for this intermediary between the dispensary, the court, the educator and the home, but the exigencies have developed a vast army of trained social workers whose functions are so important as to require persons of the highest caliber, whose mentality is capable of the highest degree of intellectual unbiasedness, whose experience is enough broader than that of those they seek to help as to enable them to find self-help, and not a weakening prop in the social agency; and whose motive is from the fullness of a cultivated heart and mind that must perfuse *share* its equipment, and large enough to gain while giving.

It is not an easy calling. Even with all these qualifications, the service must be directed by the physician, the man of science who admits that the success of his work is measured by the degree of cooperation he is able to excite and maintain in his efforts to discover disease causes, whether organic, economic, or mental; and to change the patient's way of living into a régime that means health for him, or the best adjustment possible for him.

Dr. Cabot's delineation of the whole field is classic. His various chapters on history taking, the effort to disclose the historical background, or sequence, of what the unscientific mind is inclined to regard as accidental; the searching out of real economic needs, giving the patient courage to face his own problems and solve them instead of offering him a temporary anodyne either in the form of

drugs or economic help; the teaching that not his physical environment counts so much as his own mental reactions; the steadyng of purpose and finding of personality by giving the mental derelict his bearings; the universality of fatigue, which becomes physical disease when cumulative or when referred to one particular part of the body or one weak or predisposed organ, and which becomes mental disease when accompanied by discouragement and is relieved by making a success of something, or may become social unrest when overemphasis is placed on industrial conditions and resentment aroused against those supposedly responsible and is relieved by right conditions, chiefly by right thinking and broadened activities.

"The whole human race is too big for its jobs. The industrial system is altogether too small to fit us; a large part of our powers remain unused. Therefore, the purpose of our time for rest and recreation, our evenings and our Sundays, should be to even up that balance, to use the part of us that is not used at other times."

Each chapter on these phases of social work contains the most definite help and inspiration for the social worker, and especially in its tendency to remove the overweening seriousness that envelopes some social workers and to make of society and social workers a band of cooperative self-helpers. It is most opportune in its advocacy of honest work and the fundamental and ultimate rightness of things, and the permanence and constancy of all constructive forces. Read the book.

A TEXT-BOOK OF PATHOLOGY. With a Final Section on Post-Mortem Examinations and the Methods of Preserving and Examining Diseased Tissues. By Francis Delafield, M.D., LL.D., and T. Mitchell Prudden, M.D., LL.D. Eleventh Edition, revised by Francis Carter Wood, M.D., director of the Pathological Department of St. Luke's Hospital, New York, and director of cancer research, Columbia University. 8vo., cloth, pp. 1,354, illustrated.‡

The eleventh edition of a text-book that has long been a favorite with the student and practitioner of medicine and surgery, is welcomed, since its revision brings it up to date. The revision of the chapters on tumors, on the urinary organs, on the reproductive organs of the female, and on the bones and joints, especially has been made very complete. Teachers of pathology, particularly, will appreciate the discussions of pathological physiology or pathology of function. The work includes a chapter on autopsy technique and on the methods of preparing pathological specimens.

Considering that this book includes both general and special pathology, it presents in a most concise form with many well-chosen illustrations, a most complete exposition of pathological anatomy, and it can be warmly recommended to the student and practitioner.

The discussion of the recent advances in our knowledge

Make Public Places Sanitary By Using Tile

Tile meets the requirements of modern sanitation, which is a part of the upward movement in favor of better health, better living conditions and the increased efficiency of those who labor with hand or brain.

More and more attention is being given by those in authority to public baths, swimming pools, comfort stations, and to sanitary conditions in all schools, hospitals, industrial institutions, etc.

Tiles in their various colors and forms have the qualities that meet every need in places like those named. They are clean and most attractive. Being non-absorbent, they are easily kept clean. They serve best in every way—both practical and decorative.

To the ones who select the materials for such purposes we offer a service that will be of real benefit.

Modern Chambers, 317 Collins Street, Melbourne.

SUBSCRIPTION

Domestic postage, \$3.00. Foreign postage, \$3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Canada, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS. Subscriptions may begin at any time. Volumes begin January except in the case of Volume 1, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES. Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS. Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS. When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS. The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS. Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES. Advertising rates will be sent on request.

CONTRIBUTIONS. Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene, and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS. Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER. Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

BOOKS OF THE MONTH

(Continued from Page 276)

of the pathology of the spleen and lymph nodes is particularly interesting, especially that of Hodgkin's disease and of hemolytic icterus. The effects of exposure to the roentgen and radium rays, and the explanation of their mechanism in the treatment of tumors is very clear and helpful.

HARRY JACKSON, M.D.

THE HUMAN SKELETON. An Interpretation. By Herbert Eugene Walter, Associate professor of biology, Brown University. 214 pp., 175 illustrations.*

The little volume cannot be considered as a serious scientific effort, but only as an interesting and well written story in which the bones of the body play the leading role. The beneficial results of popularizing science is doubtful. Such works are vague and superficial as far as science is concerned and therefore of necessity must attract the interest of the reader because of the rapidity of movement and a free use of the spectacular.

The author excuses the appearance of his book upon the grounds that in as much as each person possesses a skeleton of his own a better acquaintance with it should constitute a source of intellectual delight and satisfaction; and because the layman usually regards a consideration of his "insides" as an indelicate subject, and forbidding to one simply in quest of satisfaction of natural curiosity. The book is a popular equivalent of the excuses.

H. W.

THE ELEMENTARY NERVOUS SYSTEM. By G. H. Parker, Sc.D., professor of zoology, Harvard University.†

This book brings forth the results of experimental work on the development of the nervous system beginning in the lower forms of animal life. The author begins with the development of the effector or muscular system in sponges and leads up to the receptor-effector system in the coelenterates, where exists the first evidence of receptive protoplasm which in its way represents the central nervous system in higher life. In the latter there is a central nervous organ or adjuster which in the earlier forms is absent. As one ascends the scale, the author states, the nervous elements recede from the surface of the animal to a deeper location, and thus become more and more protected. With this evolution, also, is the formation of the synaptic nervous system made up of primary motor neurons extending from the central organ to the muscle and the interneuronal fibers or neurons connecting one part of the central nerve apparatus with another. To one especially interested in the anatomy of the central nervous system of man, this book makes a very interesting study.

A TEXT-BOOK OF PHYSIOLOGY. For Medical Students and Physicians. By William H. Howell, Ph.D., M.D., professor of physiology, Johns Hopkins University, Baltimore. Seventh Edition thoroughly revised. Cloth, 8vo., 1,059 pp., 307 illustrations.‡

Howell's work must still be considered the leading American text-book of physiology. The seventh edition bears no fundamental change as to the arrangement of material, or the general principles of presentation. However, the work has been thoroughly revised and brought up to date as nearly as is possible. The text is lucid and the manner of presentation is direct and forceful.

But one criticism might be offered and that is the tendency of the author to compliment the mentality of the student by not drawing general conclusions in regards to

Barbital, Abbott, And Veronal Are Identical

Both are Diethylbarbituric Acid.

BARBITAL is the official name for Veronal given it by the United States Government.

BARBITAL is the American name. Veronal is the German name.

The Abbott Laboratories

is licensed by the Federal Trade Commission to make and sell BARBITAL,

of which it is the largest producer in this country. The U. S. Army and Navy have ordered more BARBITAL (Abbott) than all other customers combined.

Barbital, Abbott,

is American, made by an all-American and always American firm. It is guaranteed to be of the highest purity and has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association.

Packages

Barbital, Abbott, is supplied in the following standard packages:

Powder in 1 ounce bottles.

Tubes of ten 5-grain tablets, packed in boxes of one dozen tubes each.

Bottles of 100 5-grain tablets.

Barbital, Abbott, will be supplied through your druggist, jobber, physician's supply house or direct, on your order, to our home office or branches. The product is right and the price is right.

Facts About The Oat

The oat yields 1810 calories per pound in the energy unit of food value. Round steak yields 890.

One-sixth of the oat is body-building protein.

The oat is rich in needed minerals—richer than beef.

It is almost a complete food.

The cost of Quaker Oats is 5 cents per 1000 calories. Meats, eggs, fish, etc., will average ten times that cost.

Quaker Oats

Are Extra-Flavor Flakes

They are flaked from queen grains only—just the rich, plump, flavorful oats. Puny grains are all discarded, so we get but ten pounds from a bushel.

The result is a flavor which has given Quaker Oats the top place the world over.

The Quaker Oats Company

BOOKS OF THE MONTH

(Continued from Page 22)

disputed points and opposing theories. Such a tendency is highly valuable for the advanced student, but it tends to weaken the beginning student in his beliefs of the accuracy of the science and its fundamental value as an aid to a proper understanding of allied subjects of medicine. However, as the author explains, the best that a text-book can hope to accomplish is to give as clear a picture as possible of the tendencies of the times. A careful review of the text will assure one that such has been accomplished in an admirable manner.

Physiology is a rapidly growing subject which often requires readjustment of its theories. The thinking student should rapidly appreciate this condition and learn to evaluate data and draw conclusions from the facts or evidence presented. Dogmatic statements and submissive acceptance of such, especially where theories are concerned, can never advance science. Hence, the criticism offered above applies more to the reader than to the author of the book.

H. W.

THE PRINCIPLES OF MENTAL HYGIENE. By William A. White, M.D. With an introduction by Smith Ely Jelliffe, M.D., Ph.D.*

This is a book of which the last chapter may be read first without a loss of interest in the story as it gives a comprehensive view of the author's thesis which finds in primary physical reactions to environment the beginnings of motives, and in the conditioned and coordinated reflexes the groundwork of personality. The integration of the individual is accomplished by stages in the biologic development: there is first the simple physical reaction to environmental stimuli; then comes the physico-chemical response to stimulation; later on functional and psychological adaptation; and, finally, integration and social adjustment.

The course of development depends upon the needs of the organism as well as upon the manner in which it reacts to outside influences. Motives grow out of the reactions, and "conduct" is the sum total of the whole biologic process, the motives for the most part being unconscious, instinct in most cases governing rather than reason. Causes for variations in conduct are to be sought in the history of the individual as an atypical unit rather than as a conscious violator of the established standards of the herd.

For this reason the custom of present day society of punishing criminals by violence and repression is unintelligent, for just as arrested progress at certain stages of physical growth results in developmental defects, so at certain transitional periods may the psyche fail of integration and thereafter be limited to the psychological level where progress was arrested. Social inefficiency really means mental deficiency, the defectives stopping at a lower level. Asylums, prisons, and poor houses are filled with the failures in life, social members who cannot live in the community as useful citizens; they are incapable of adequate adjustment.

It is the function of mental hygiene to study these conduct reactions, institute corrective measures where there is possibility of improvement, and, also, to determine when such individuals can never arrive and so spare society the tremendous waste in futile efforts at reform.

Perhaps one of the most interesting phases of the argument is in the relation of physical disorders to the

"Men have gone sixty-three days without food and a week without water, but they cannot last more than ten days without sleep."

MOST Physicians, Nurses, Public Health officials and Industrial Welfare Workers these days are exerting their every effort to spread the gospel of sound, restful sleep—

*Vital to Health, Efficiency,
Happiness and Longer Life*

As an active, reconstructive process and as a restorer of vitality, the importance of the **right kind of sleep** cannot be ignored. Sound, restful sleep means sleep of **complete** relaxation; and such a condition cannot be brought about unless one's bed **invites it**.

For two generations Simmons Beds have been designed and **built for sleep**. Strong, substantially constructed, noiseless and supremely comfortable, they have become the National Standard of value and comfort, wherever Beds are displayed, sold, used and talked about.

Catalogs picturing and describing Simmons Beds for Industrial, Recreation Camps, Schools, Hospital and Public Institutions, will be mailed promptly upon request. Address

THE MENTAL HYGIENE OF CHILDHOOD. By William A. White, superintendent, Saint Elizabeth's Hospital, Washington, D. C.*

The number of human derelicts, the proportion of men and women incompetent to earn a decent living, of moral weaklings, nervous and mental wrecks furnish a formidable argument against formerly accepted methods of education for here as elsewhere failure means lack of proper adjustment. So large a percentage of failures cannot be charged to inherent defects in the individuals themselves and the only solution of the problem lies in the development by means of "psycho-analysis" of a mental hygiene of childhood.

This the author has done. The child from the first is controlled by two fundamental instincts, the ego-instinct and the pleasure-pain instinct, always in constant play and also in constant conflict, the picture of development being a constant play of activities conditioned by these fundamental instincts but in which the sex instinct plays an increasing and predominant rôle. "All those warring tendencies battle for ascendancy and drive it along the path of development." The influences that come out of the past and the early environment are of tremendous importance; the first cannot be changed, but "the latter are capable of great modification and offer the field in which mental hygiene is operative."

The author's treatise emphasizes the importance of the developing sexuality of the child and the antagonism between parents and children, matters not usually taken into consideration. The concept that the child is asexual cannot be a basis for intelligent dealing with children. If its sexuality is ignored, these perfectly normal tendencies may go astray and if too many inhibitions are set up they may in later life result in the serious handicap of an infantile sexuality which has never had a chance to grow up. It should be recognized as a great force to be directed and used for constructive ends. Herein lie some of the blunders which account for many of the maladjustments of society.

"Now comes along science, which has illuminated so many things in this age of efficiency, and throws its light into the dark places of age-long customs." We may expect that many errors will be disclosed and the correction of the faulty practices which grew out of them will result in a better society.

YEAR'S WORK OF ROCKEFELLER FOUNDATION TOLD BY VINCENT

A review of the demonstrations and studies in public health made in 1918 by the Rockefeller Foundation, prepared by George E. Vincent, president of the Foundation, makes note of the fact that campaigns to encourage sanitation were carried on in twelve states of the Union and in twenty-one foreign states and countries.

The year's work included an extended campaign against tuberculosis in France, which centered in an endeavor to coordinate the existing agencies for combating the disease. France does not have organizations of the same national scope as the United States through which may be found channels for the education of the public in health standards. To overcome this absence of cooperative activities, the Rockefeller Foundation undertook and successfully demonstrated the advantage of team-play. The investigations directed against hookworm were continued.

THE CARE OF THE MOUTH

"**A** CHILD naturally rebels against mouth cleansing while it is ill or peevish, and therefore if some more attractive and efficient way can be found to accomplish the same result, we ought to take advantage of it.

"Adams Pepsin Chewing gum seems to offer the best relief. It is attractive to the child and through its use at stated intervals the little one is led to effectively do two things that are most important in keeping the mouth and tongue clean: (1) a stimulation of the flow of saliva, and (2) the beneficial movement of the tongue, which is a most efficient cleanser through its mechanical action alone."

Thus writes a well known Brooklyn specialist in diseases of children, in an article in "American Medicine."

His suggestion aroused the interest of a great many physicians, who realized from many an unhappy experience, the difficulty of cleansing the mouths of sick and peevish children by the use of ordinary washes and gargles.

Promotes 44-Hour Week for Labor

At the closing session of the annual convention of the American Federation of Labor, June 23, the Federation pledged itself to obtain a general forty-four-hour week for workers of all crafts throughout the United States, and for employees in Government service.

Placement Bureau for Nurses

The American Red Cross provides an employment service for nurses returning from service with the military forces. Nurses are referred to institutions having vacancies, or service is given to institutions needing nurses. Headquarters for the service, it is announced, will be the Bureau of Information for Nurses, at the Atlantic Division of the Red Cross, New York City. The bureau is not an employment agency, but is organized to serve as a clearing house for nurses and institutions.

"AMERICAN CHILD" A NEW JOURNAL

As successor to the *Child Labor Bulletin*, the Child Labor Committee announces that it will publish *The American Child*. The first issue of the new magazine names the following representatives of child welfare bodies as editors: Owen R. Lovejoy, editor; Raymond G. Fuller, managing editor; E. N. Clopper and Ruth McIntire, associate editors; Wiley H. Swift and Josephine J. Eschenbrenner, contributing editors. The new magazine will deal with problems of child welfare, and will present the results of investigations and research by experts on questions of child welfare. The journal will be issued quarterly.

FIRST TASK OF RED CROSS LEAGUE

War on typhus with a view to preventing the spread of the dread malady from Poland, where 100,000 persons are down with the disease, to other countries of eastern and southeastern Europe by the League of Red Cross Societies of the World, is the first great health work on behalf of humanity which the organization, formed only a few weeks ago, has set out to perform. The Supreme Economic Council has appointed a committee of British, French, and Italian representatives to confer with representatives of the League of Red Cross Societies, regarding plans that will be submitted to the governments of the countries of eastern Europe.

COLUMBIA UNIVERSITY PUTS PHYSICAL EDUCATION ON SOUND BASIS

Corrective medical service and advice has been made available to the students of Columbia University, and a permanent, resident staff of physicians and nurses will be present to furnish the necessary medical attendance.

Columbia has recently adopted a program of physical education for the training, instruction, and medical supervision of the student body, with the purpose of developing and maintaining a high average of health.

The freshman student, when he enters college, will come under the supervision of the university medical staff. During the full period of his school course the medical supervisors will watch out for his physical well-being.

The new system has been developed under the direction of Dean Herbert E. Hawkes, Dr. W. H. Castline, and Dr. George L. Meylan. The university restaurant has been placed under the supervision of Prof. Charles T. MacFarlane, whose duty it will be to see that a properly balanced, wholesome diet is provided for students.

SCIENTIFIC-EFFICIENT ECONOMICAL *Pain Relieving Methods*

You appreciate the value of sunlight as a therapeutic agency; you know about the pure white rays, the violet rays and the ruby screen. The Sterling Therapeutic Lamp combines all these agencies in an efficient and economical manner.

STERLING THERAPEUTIC LAMP

"The Light That Heals"

Has proved one of the most efficient methods of relieving pain; its effect is soothing and analgesic; its rays are germicidal. The warm, soothing, soft rays penetrate and vitalize every cell and tissue, new cell growth is stimulated; the body is refreshed and vitalized.

In rheumatism, neuralgia, neuritis, lumbago, in nervous conditions and a score of other symptoms and diseases, including skin and scalp disease, the Sterling Therapeutic Lamp is invaluable for the relief from pain, inflammation and for corrective purposes.

With stand it is ideally adapted for additional use as a spot light for operations and examinations.

Widely used in sanatoriums, physicians' offices and hospitals; special sizes are adapted for the use of patients under the supervision and direction of the family physician.

Write for our interesting illustrated Booklet showing the various sizes and uses of the Sterling Therapeutic Lamp.

NEWSPAPER INDORSES A. M. A. PETITION

The resolution approved by the five Councils of the American Medical Association calling upon Congress to appropriate not less than \$1,500,000 for a scientific campaign against the influenza germ, has prompted an editorial indorsement in the Columbus (O.) *Citizen*.

"The proposed appropriation," comments the *Citizen*, "as a strictly business proposition, is an extremely low rate of insurance for the prevention of future loss."

BUFFALO ISSUES INFLUENZA REPORT

The city of Buffalo, N. Y., is one of the first large cities in the United States to complete a municipal survey of the influenza epidemic, its incidence, severity, fatality, and after-results. Acting Health Commissioner Frank C. Gram, who related the results of the survey at the recent meeting of the American Medical Association, declares that popular fears of health impairment among persons who were victims of influenza are to be discounted. He reports that 33,880 persons were afflicted with the disease between October 1, 1918, and March 31, 1919. The deaths numbered 3,179. There were 748 cases with sequela arising from influenza. Commissioner Gram is making a follow-up analysis of the sickness and disease that has been attributed to earlier cases of influenza.

MEDICAL AID FOR SERVICE MEN

If any disabled service man who is considered by the Bureau of War Risk Insurance to be as much as 10 percent disabled, will get in touch with the Federal Board for Vocational Education, Washington, D. C., or with any one of its fourteen branch offices, the Federal Board will place them in educational institutions, when education is necessary and feasible, where suitable trades or occupations will be taught them according to their individual experience, capacities and preferences. A disabled man so incapacitated that he cannot take up his old occupation will be allowed to choose any occupation or trade which he thinks he would like to follow, subject, of course, to be assured that the man is fitted to pursue the occupation or trade elected. MODERN MEDICINE will furnish the addresses of district offices upon request.

to approval by the Federal Board, which is interested only

ASKS A. M. A. TO PUBLISH MEDICAL JOURNAL FOR LAYMEN

The American Medical Association should publish a medical and surgical journal for the lay reader, written in the language of the layman, urged Dr. Hugh T. Patrick, of Chicago, at the annual convention of the Association, who introduced the following resolution:

"That the trustees be requested to consider the feasibility of publishing a journal of surgery, and also a journal of health and medicine for lay readers, and that the house express itself as sympathetic to both ventures, if the trustees find them to be practicable."

That the Press Bureau of the Association may be discontinued and the work it has done be left to other organizations, is recommended in the report of the Council on Health and Public Instruction, presented by Dr. Victor C. Vaugh, of Michigan, chairman. The report states:

"It seems evident that the propaganda period in public health work is past. Many of our national health organizations, either special or general, as well as many of our state boards of health are now sending out press bulletins.

HAY-FEVER

Successfully Prevented

THE use of POLLEN ANTIGEN—*Lederle* has successfully prevented hay-fever in 81.6% of 9,000 cases, including vernal and autumnal types, during the four years 1915 to 1918 inclusive. These favorable results were reported from 44 States in the Union, from Maine to California; and from Canada, Porto Rico and Cuba.

POLLEN ANTIGEN—*Lederle* possesses these advantages:

1. Prepared from pure pollen grains.
2. Standardized serologically to determine antigenic power.
3. Will not deteriorate on long standing.
4. Manufactured under U. S. Government license.
5. May be used without preliminary diagnostic tests.
6. Will NOT cause artificial sensitization.

POLLEN ANTIGEN—*Lederle* is supplied in the following packages:

Complete Series,	Doses 1 to 15 . . .	\$15.00
Series A . . .	Doses 1 to 5 . . .	5.00

Housing Survey in Coal Districts

As a result of the recent report submitted by Dr. Emery R. Hayhurst on the health of coal miners in Ohio, a special state commission has been created to study and report on housing conditions in the coal mining counties of Ohio, and to suggest remedial measures.

PUBLIC HEALTH AND RABIES

"From England on April 24th, there came to the American press sensational reports of an outbreak of rabies, so widespread that a condition akin to panic was created," says the *Scientific American*, in the June 14th issue, which contains an account of the situation in England and a discussion of the disease with relation to the public health problem. The article follows:

"Dealers in dog muzzles were swamped, and were accused of profiteering. Dogs were stoned in the streets, and owners put their special pets to death by painless processes.

"All this brings to mind very vividly England's remarkable record with reference to this disease, for it has been years since there has been a case of hydrophobia in the British Isles. This record suggests some important conclusions with regard to public health, as a world problem.

"England's remarkable showing is due to strict dog laws and their enforcement. From 1887 to 1896, there was an average of 238 cases of rabies a year in England. In 1901 a law was passed that all dogs imported into the country must be licensed. They were then quarantined under observation for six months by the government. All stray dogs were killed. As a result there has been no case of rabies in England since 1903 until the outbreak of April, 1919. It is rumored that the disease was introduced by soldiers' dogs brought across the Channel in airplanes to evade the quarantine.

"Fully to comprehend the importance of quarantine, as a protection to public health, one needs only to recall the cause of rabies and its means of transmission. A minute protozoan or one-celled animal, discovered by Negri in 1904, and named after him the Negri bodies, is the direct cause of the disease. The presence of these Negri bodies is detected in the brain or spinal cord of a suspected animal by mounting a portion of the brain or spinal cord on a microscopic slide and staining it with a particular fluid, called the Gierke's stain. This stain is taken up by the Negri bodies and differentiates them clearly from the other brain tissue. Their prevalence in the brain or spinal cord definitely determines the fact that the animal was a victim of rabies. This method of examining the brain or spinal cord of a dog, who has bitten some one, at once, instead of keeping the suspected animal under observation for a considerable time, enables the victim to begin treatment immediately, thus greatly increasing his chances of recovery.

"One of the results of the war has been that governments have taken up health activities on a scale never before attempted. The health of the community is no longer a question of the individual, but of the individual and his relation to his neighbor.

"The recent outbreak of hydrophobia in England after her long immunity, should give pause to New York City with a dog population of 500,000 and less than 100,000 of them licensed. In one year, 1915, moreover, there were over 3,500 persons in New York City bitten by dogs. No after-war problem is more important than this one of public health and the rigid enforcement of quarantine, that proved so effective in protecting England against the dread disease of rabies."

SALVARSAN AND NEOSALVARSAN (ARSPHENAMINE-METZ) (NEOARSPHENAMINE-METZ)

We have greatly improved the methods of manufacture of these standard remedial agents. Official tests show they possess a relative fixity of arsenic content entirely in keeping with the original products.

We have no hesitation in asserting that Salvarsan and Neosalvarsan are now the arsenical preparations *par excellence*.

We have reduced the prices to such an extent that these valuable drugs are now available for much more extended use in private practice.

War Surgery Monthly Suspends

Publication of the *Review of War Surgery and Medicine* by the office of the Surgeon General of the Army was suspended with the June issue.

Colonel Strong in Hygiene Bureau

Colonel Richard P. Strong, M.C., United States Army, of Cambridge, Mass., has been named as acting director of the Bureau of Hygiene and Public Health of the League of Red Cross Societies, at Washington, D. C.

FRENCH SOCIETY ELECTS AMERICAN PHYSICIANS TO HONORARY MEMBERSHIP

The Société médicale des Hopitaux de Paris recently elected the following American physicians as honorary members of the society: Dr. Beverly Robinson, of New York; Dr. William S. Thayer, of Baltimore; Dr. Alexander Lambert, of New York; Dr. Simon Flexner, of the Rockefeller Institute for Medical Research, New York; Professor Morton Prince, of Tufts Medical College, Boston; Dr. James T. Case, chief of the radiological service of the American army in France. At the same time five British physicians were elected to honorary membership, as follows: Sir Bertrand Dawson, Sir Almroth Wright, Sir William Leishman, Sir Thomas Barlow, and Sir Dyee Duckworth.

EUROPE NEEDS PREVENTIVE SCIENCE

The increase in the prevalence of the commoner kinds of afflictions in southern Europe during the war and the recurrence of epidemics in several countries, have made the need for preventive measures so pronounced, says Lieut.-Col. Homer Folks of the American Red Cross, that a modern public health program becomes vitally necessary in meeting the emergency.

Colonel Folks, who served as director of civilian relief in France, and as representative of the American Tuberculosis Commission, gave his impressions of the health situation abroad in an address recently before the annual conference of Health Officers of the State of New York.

"Although some of these countries," he said, "may be termed permanent headquarters for serious epidemics such as typhus and cholera, nevertheless the big job in public health in these countries, as with us at home, is dealing with diseases everywhere prevalent but to the extent and gravity of which we have become partly unconscious, such as tuberculosis and infantile diseases."

"The fact that disease persists in these countries does not mean that natural conditions are bad or that the people prefer filth and disease. It means to a great extent that they never had the facilities for getting and keeping clean. It follows from this that the cleaning out of these permanent centers of disease is not impossible, and that it is probably more practicable to clean out these centers of origin than to erect any sanitary cordon across Europe to catch and stop disease when it has gotten under way."

Bulletin No. 9 of the Iowa State Board of Health is devoted to discussion of "Better Housing in Iowa," and includes brief statements by Governor W. L. Harding and Guilford H. Sumner, executive and secretary, Iowa State Board of Health.

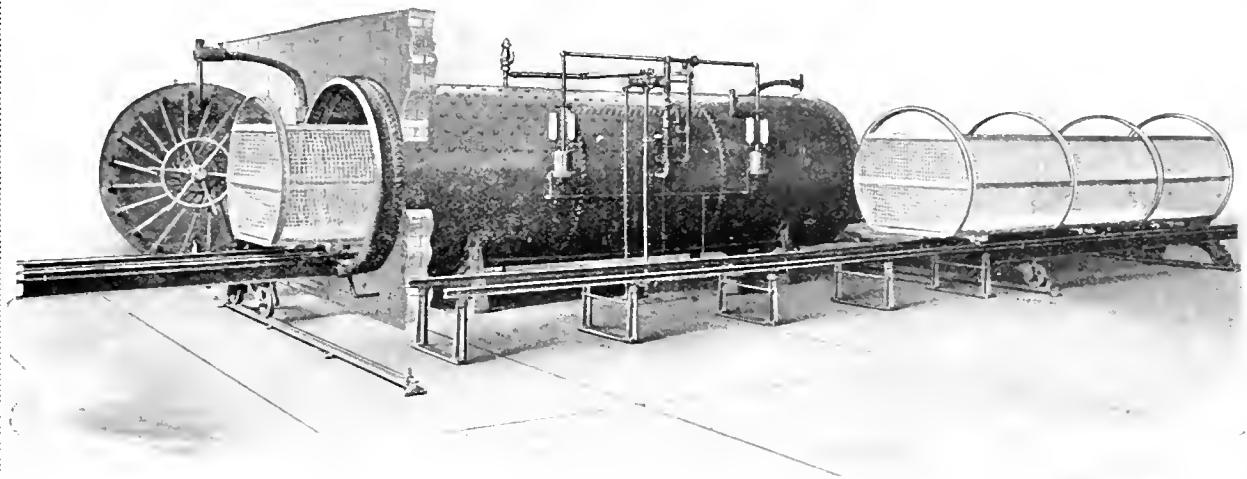

The *Kallikaks*, of Kansas, a study of the feeble-minded in Kansas comprises a special bulletin detailing the results of the findings of the Kansas Commission on the Provision for the Feeble-minded.

Physical Conditioning

So many patients, especially women, lack the initiative to follow general advice regarding exercises, dietary, and personal hygiene. Physicians acquainted with my work are constantly referring these cases to me for physical and mental "conditioning."

A woman can often inspire her sex to be and to do and hold her to this inspiration by regular correspondence as men cannot.

Every pupil's requirements are studied individually, and each is directed according to her needs and her strength.

This cooperative work with the medical profession is giving results highly gratifying to both physicians and patients.

I shall be glad to assist you with patients who need conditioning through exercise, diet, breathing, correct poise, relaxation, reduction of flesh, or building of flesh.

Susanna Cocroft

Cost of Food Climbs 92 Per Cent

According to figures compiled by the United States Department of Labor, the cost of twenty-two articles of food in May, 1919, for the United States as a whole, was 17 per cent higher than in May, 1918, and 92 per cent higher than in May, 1913.

Form Health Conservation League

Several physicians, dentists, nurses, and druggists of Buffalo, N. Y., are organizing a Health Conservation League, to have for its object combined action by the four professions when occasion arises, to work for public health, and to influence public opinion in matters pertaining to public health. Dr. Albert I. Lytle, president of the Eighth District Medical Society, is one of the promoters of the League.

TAX ON NARCOTICS BURDENS PHYSICIANS

Governmen officials in the Department of Internal Revenue are held responsible for efforts to make the Harrison Drug Law a revenue-producing act, by the report of the Council on Health and Public Instruction of the American Medical Association. The law was not intended to be a revenue-producing measure, it is contended, and attempts to make it so, are declared detrimental to the members of the medical profession and to the public health.

The portion of the report dealing with the question reads as follows:

"During the past year the registration tax for physicians under the Harrison Law has been increased from \$1 to \$3. You are all familiar with the history of the passage of this law. Enacted by Congress to carry out our international obligations in compliance with the recommendations of the Shanghai Commission on the Control of the Opium Traffic, it was put in the form of a revenue measure simply to give Congress jurisdiction. *The Journal of the American Medical Association* cooperated heartily and cheerfully in securing the passage of this measure. The medical profession of the country as a class accepted the imposition of a nominal registration tax and the inconveniences connected with the operation of the law as necessary accompaniments of any practical plan for the control of legitimate traffic in habit-forming drugs. In the revenue bill for 1918, however, a new tax schedule was provided increasing the tax on physicians from \$1 to \$3. This is simply an effort on the part of the Department of Internal Revenue to make a revenue-producing measure out of what was originally and legitimately intended for a restrictive law for the public good. The law will not be any more effective in its operation under a \$3 tax than it was under a \$1 tax while it will impose an additional burden of about \$300,000 on physicians. The only justification of the law is the public good. The expenses of its administration should be paid out of the public funds and not out of a special tax levied on one particular class. While the increase in the amount of the tax might be justified as a war measure, now that the war is over there is no possible justification for it. The Council, therefore, recommends that the House of Delegates record its emphatic disapproval of this unjustifiable attempt to exploit physicians and that it demand the reduction of the registration fee for physicians to a nominal amount."

Even in the meanest sorts of labour, the whole soul of a man is composed into a kind of real harmony the instant he begins to work.—Carlyle.

NOTES AND COMMENT

NATIONAL AND STATE HEALTH POWERS

HERE is such confusion in the public mind about the duties of the state and national government in all matters of public concern that it is natural to find the same confusion in regard to health. Demands are made upon the Federal government without regard to certain fundamental divisions of power between the states and the Nation, and demands are likewise made upon the states for action which could only be effective legally and practically when done by the Federal government. Demands are also made upon the local governments without much regard to their legal power to act.

MODERN MEDICINE presents in this issue two papers on the relationship of the states and the Nation, one written by Dr. Frank A. Goodnow, president of the Johns Hopkins University, and the other by Dr. Allan J. McLaughlin, assistant Surgeon General of the United States Public Health Service. Both writers are authorities, one on the side of practical administration, and the other on the side of constitutional and administrative law.

These remarkable papers delimit the powers of the states and the Nation so clearly that they deserve careful study. Constructive criticism may be more intelligently directed if we know the fundamental division of powers which the courts will sustain under the conditions.

The Federal government is a government of delegated powers. Those powers are written out in the Constitution of the United States and if a power cannot be found there, either expressly given or implied, the Federal authorities cannot act. All powers not so delegated to the Nation

are left to the states, and are retained by the state or imposed by the state on local governments. So far as the Nation is concerned, then, we must look to the Constitution of the United States to see what powers have been expressly or impliedly granted to the Federal government.

Doctor Goodnow finds that no power over public health matters has been expressly granted except in the territories and in the District of Columbia. That is natural enough when it is remembered that public health matters were scarcely thought of in 1787 when the Constitution was framed. He finds that there are three sources of power: (1) the power to regulate commerce between the states; (2) the taxing power; and (3) the treaty power, from which the power to make health regulations may be implied.

Of these the commerce and taxing powers are the most important at present because they have been interpreted. We already have interstate quarantine and pure food laws under the commerce power; and child labor and narcotic laws, such as the Harrison Act, under the taxing power. International labor and health regulations are proposed under the Peace Treaty, which it is expected will become more than a mere recommendation to the states.

"Insanitary conditions," says Doctor Goodnow, "as a matter of fact, are no longer of merely local concern. Epidemics are not respecters of state or even national lines. A keener realization of this fact will unquestionably have the effect of causing a broader interpretation of existing powers and may well result in constitutional amendment where such broader interpretation is not possible."

The paper by Doctor McLaughlin presents the

same idea from the standpoint of administration. It recognizes conditions as they are, and points out how the national, state, and local governments may work together so as "to insure the covering of the entire field of public health between them. All gaps should be covered by one or the other jurisdiction and in twilight zones there should be the most complete understanding of a frank policy which would preclude overlapping, duplication, or conflict."

As a remedy for the present indefiniteness of authority, Doctor McLaughlin suggests a partnership between the Nation and states on the principles already established by national aid to roads, education, and the venereal disease campaign.

"Let us waste no time," he says, "in a futile effort to delimit accurately the police power and authority of each of these three jurisdictions, but let us leave such discussion to the academicians. As practical men let us disregard the theoretical boundaries of varying police jurisdictions and attack each health problem by joint concerted action according to a nation-wide program, remembering that the spread of disease recognizes no boundaries,—local, state, or Federal."

COMPENSATION FOR OCCUPATIONAL DISEASES

WHAT is an occupational disease? There is perhaps more futile discussion based upon the use of this term than on any question in the realm of accident or health insurance. The reason is found in the fact that there are few occupational diseases clearly distinguishable from other forms of disease.

Occupational diseases shade into other forms. Tuberculosis may be occupational or otherwise. Lead poisoning is almost always occupational, but not necessarily. Caisson disease and "phossy jaw" might be designated as strictly occupational with little likelihood of occurrence outside of industry. We might define an occupational disease as one which has its cause in an occupation, but that would not take care of the cases of disease which are not caused but are aggravated as a result of an occupation. If we accept the latter as a part of the definition, we have thereby claimed a large part of disease as occupational.

Nervous disorders of a telephone girl, or tuberculosis in a dusty trade should apparently be classed as occupational; but who knows whether the cause in the particular case may not be found on the outside, in the conditions of living or otherwise?

Workmen's compensation laws have brought the whole issue to a focus and commissions are

now struggling in almost hopeless confusion with the question of compensation for occupational diseases. Each attempt to clear up the confusion drives the commissions into more intricate questions, simply because there is no logical place to stop.

It is easy enough to grant compensation for lead poisoning. The responsibility of the industry is clear because men do not generally handle lead outside. But why compensate for lead poisoning and not for tuberculosis caused by a dusty trade? If compensation is given for tuberculosis, what allowance shall be made for other causative factors? Why compensate for loss of eyesight by accident and not when caused by slow process due to bad illumination? Must we always concern ourselves with the spectacular, and forget the disasters caused by slow processes?

The way in which the states are beginning to attack this problem is set forth in this issue by Mr. Carl Hookstadt, of the United States Bureau of Labor Statistics. He finds that six states are attempting to give compensation for injuries due to disease; of these, only the state of Wisconsin names specific diseases which are compensable. At present there are twenty diseases designated. The other states use broad terms to cover all injuries in employment, and the commissions and courts do the rest.

The experience thus far gives the basis for classification set forth by the author, as follows:

1. Diseases due to gradual absorption of poisons (lead poisoning).
2. Diseases in which the poison or germ enters the system through a break in the skin (anthrax).
3. Skin affections from acids or other irritants (eczema, dermatitis).
4. Diseases due to fumes or dusts entering the system through respiratory organs (tuberculosis, gas poisoning).
5. Diseases due to vibrations or constant use of particular members (neuritis, telegrapher's cramp, housemaid's knee).
6. Miscellaneous diseases (caisson disease, miner's nystagmus).

It will be seen from this classification that compensation is allowed in cases of quick development where the cause is clear; but it will be apparent that all of the diseases for which occupations are responsible, in whole or in part, are not definitely determinable and compensation under existing systems cannot be granted.

As a result of the necessary limitations, only a small fraction of disease is compensable. In England, in 1914, only 5.8 per cent of the total workmen's compensation resulted from occupational

diseases, while experience in this country runs far less. It will be apparent that as a means of meeting the problem of sickness, compensation for occupational disease is entirely inadequate. Disease causes several times as much loss as accidents, while compensation for occupational diseases under the present system amounts to only from 2 to 5 per cent of accident compensation.

THE REPORT OF THE ROCKEFELLER FOUNDATION

THE review for 1918 of the work of the Rockefeller Foundation by George E. Vincent, president of the Foundation, is all that could be desired in a public report. It is readable and inspiring; it covers the ground; it gives an outline of world-wide health problems and a vision of world-wide health organization. It is such a report as the average layman as well as the physician would read with sustained interest, which is more than can be said for very many of the public documents on health.

Probably a large part of the interest in this report comes from the fact that the president had interesting things to report,—plenty of them: the brief summary of the activities of the Foundation indicate this. To give the world-wide sweep of the health movement, we quote from the report seventeen activities in which the Foundation was the promoter or an important factor:

"(1) Extended a campaign against tuberculosis in France; (2) conducted demonstrations of malaria control in Arkansas and Mississippi; (3) helped to check a yellow fever epidemic in Guatemala; (4) made investigations and surveys, and inaugurated measures against the same disease in Ecuador; (5) continued or began hookworm control, and encouraged sanitation in twenty-one foreign states and countries and twelve states of the Union; (6) entered into comprehensive co-operation for improved public health organization in Brazil and Australia; (7) supported a school of hygiene and public health which was opened in October in connection with the Johns Hopkins University; (8) continued to contribute to various war-work agencies until the total given since 1914 reached nearly \$22,500,000; (9) pushed forward the fifteen buildings of a new medical center in Peking; (10) increased the funds of twenty-four missionary hospitals, medical and pre-medical schools in China; (11) cooperated with South America institutions in establishing certain departments of research and teaching; (12) maintained sixty-eight fellows and scholars from the United States, China, and Brazil who were studying at American medical schools; (13) supported

studies in mental hygiene; (14) continued appropriations for the after-care of infantile paralysis cases; (15) made additional gifts to the Rockefeller Institute for Medical Research; (16) lent expert members of the Foundation staff for various services; and (17) brought to an end studies in industrial relations."

As a program for the future, President Vincent cites the general aim of the Foundation as expressed in its charter: "The welfare of mankind throughout the world." "Each country," he says, "will be urged to contribute its best achievements to a common fund upon which all lands may draw."

INFANT MORTALITY

STATISTICS of the deaths of infants during the first few days after birth give a dependable index of the care provided for mothers and babies at birth and before. The total infant mortality in proportion to births as an index is dependent upon the accuracy of birth statistics and there are few places where such statistics are accurate.

The mortality statistics for 1916 show that 164,600 babies died within the first year after birth and of these 52,418 lived less than a week, and 75,583 less than a month. Nearly 46 per cent did not live to be thirty days old.

Informative comparisons are possible between cities and rural communities and these comparisons indicate the value of the statistics. We would expect, for example, the proportion of infants in the rural districts who died within thirty days to be greater than in the cities because of lack of medical facilities in many rural communities. The figures prove the conclusion.

Out of 73,551 deaths in rural districts of infants under one year 36,182, or almost 50 per

COMPARISON OF DEATHS AMONG INFANTS ONE MONTH OF AGE AND ONE YEAR OF AGE IN CITIES AND RURAL SECTIONS IN 1916

	Total deaths under 1 year of age		Total deaths under 1 month of age	
	Rural	City	Rural	City

Congenital debility	7,800	8,481	5,280	5,346
Injuries at birth	2,319	3,955	2,287	3,912
External causes	1,152	969	346	301
Diseases ill-defined or unknown	3,982	560	2,308	284
All other causes	4,065	5,221	1,202	1,390
All causes	73,551	91,109	36,182	39,401

cent, died within thirty days; while in the cities out of a total of 91,109 infant deaths occurring under one year, 39,401, or a little over 43 per cent, occurred within one month from birth. The average percentage for the preceding five years was 40 per cent for cities and 47.1 per cent for the rural districts. The causes of infant deaths also offer interesting features of comparison.

These figures significantly show where the emphasis should be placed in infant welfare work. Where the great losses occur, preventive work should be intensified.

THE TRAINING OF MEDICAL HOSPITAL SUPERINTENDENTS

WHAT motives or what processes of thought influence medical men to take administrative hospital positions? Do many of the younger men who enter medical college think, when embarking on their scientific course, that it is to lead them into a life work of hospital management? Yet an increasingly larger number of medical men each year go or drift into administrative work. Is their action the result of choice or accident?

The industrial and business worlds have by experience developed definite composite character standards for successful executives. The basic requirements of forcefulness, clearness of mind, quick decision, and firmness apply as much to hospital superintendents as to managers of industrial plants or of business organizations. Fundamentally the problem is the same: to produce the maximum amount of service at the minimum amount of cost.

The reservoir of men from which the business world has to draw is very large. The hospitals are restricted to a comparatively small group, first, because they cannot compete with business concerns in payment of compensation; second, because they require of their managers a considerable amount of technical knowledge which is very seldom possessed by persons without a medical education. Although many lay persons have proved themselves to be excellent hospital superintendents, the modern tendency is unmistakably toward limiting the field to graduates of medical schools. Their "right to monopolize" hospital management is on par with the "right" of engineers and chemists to manage industrial plants. But right involves responsibility, and this leads to a consideration of the problem of training medical men for administrative duties.

Prior to our entrance into the Great War some of our medical schools adopted the five-year course. The application of the new curriculum was postponed on account of the war exigencies.

The post-bellum period of reconstruction will give added momentum to the movement for a prolonged medical course. The majority of our first-class schools will add the fifth year and will devote it chiefly to bedside instruction in hospitals. Students desiring to devote themselves to a career of laboratory research will probably be allowed to utilize the additional year in the laboratory instead of in the hospital wards. Likewise, those wishing to select the field of public health for their life's work ought to be given the opportunity to specialize in studies that will fit them for their selected tasks. Is it not feasible to establish a special course for those who would wish to fit themselves for the duties of hospital managers? The very existence of such courses would act as an axis of crystallization for those students who feel more or less indistinctly a preference for work in hospitals over the practice of medicine.

The courses offered would embrace such subjects as business management, efficiency tests, the science of accounting and finance, the understanding of values in the many kinds of goods in which the hospital is interested, and then, of course, instruction in the problems of hospital management. The last mentioned will be conducted by successful hospital administrators, with whom arrangements could be made to teach the students at the hospital and put them to practical tasks. One year's study will not, of course, develop young men into mature executives but it will serve two purposes: (1) it will eliminate those who are unfit for executive positions and save them future failure; and (2) it will give an opportunity to those with executive abilities to train their native faculties for the successful discharge of their duties in the future. Many hospitals will be glad to avail themselves of the services of these partially trained graduates who would be more valuable to them from the very outset than persons who had had no administrative training whatever and are unfamiliar with hospital problems. At the same time the young graduates will be enabled from the beginning to earn a definite salary and that in a position which will lead to further advances along those lines in which they desire to specialize.

A general discussion of this subject is desirable. It may be that the suggestion of linking hospital management courses with medical college curriculums is not practical; it might perhaps be better to establish training schools in connection with some of the hospitals, just as we have training schools for nurses. The subject, however, is a vital one and deserves careful thought and discussion.

E. H. LEWINSKI-CORWIN, M.D.

BETTER HEALTH THROUGH BETTER HOSPITALS

BY THE REV. CHARLES B. MOULINIER, S.J., PRESIDENT, CATHOLIC HOSPITAL ASSOCIATION, MILWAUKEE WIS.*

FOR the past year and a half Dr. John G. Bowman, director of the American College of Surgeons, and the author, as president of the Catholic Hospital Association, have been traveling throughout this country and Canada, trying to make better hospitals, trying to tell the medical profession, the hospital workers, and the people that hospitals throughout this continent should be better, the whole objective in all our work having been just one thing—the benefit of the patient, better care of the patient. No credit for this concept of the movement is due to any one person concerned because a moment's thought makes evident that the medical profession, the nursing profession, and the whole personnel of the hospitals are for the patient first, last, and all the time. People do not fall ill and become patients for the benefit of the medical profession, or to accommodate the hospital people, or the nurses. It is just the other way around; all these agencies are arranged to meet the needs of those who are sick and their organizations are so planned as to meet them in the best possible way.

Service Should Be Uniform

That these several agencies should get together on some of the fundamental principles of such medical organization, plan their efforts to meet every phase of the situation, and that without duplication of effort or overemphasis of one phase to the neglect of the other, is only the part of common sense.

What does this getting together on fundamentals mean? Doctor Bowman has told you that it means organization, records, adequate laboratory service.

It has been considered in terms of physical equipment—definite types of buildings, certain kinds of food, special installations of laundries, and all the other details incident to efficient hos-

100 PER CENT MEDICAL SERVICE

Unity in the standards of the three basic units of hospital service—which are the medical profession, the nursing profession, and the hospital profession—is the first principle of modern medical practice. It is not only the hospitals that must be standardized but the medical profession as well.

The hospitals are going to see to it that every patient who enters will get as nearly 100 per cent of service as can be brought about. From every standpoint—service of the laboratory, keeping of records, relations with patients—hospitals and physicians will be held to this high standard.

and it is the physician who must get to the patient the medical knowledge of the day. The hospital, the building, the food, the heat, the beds, the equipment, the technicians are all but means to the end of getting the carefully gathered scientific knowledge and skill of the medical profession into the system of the patient. Until unity of purpose and action in these matters is achieved on the part of the medical profession so that they will make records, keep records, demand and co-operate in the institution and maintenance of the most efficient care and restoration of the sick, of what avail are the deliberations of earnest bodies of hospital workers, regulation of hospital management, or even state and Federal legislative acts?

Team Work Is Necessary

The physician in the past has been an individualist. As the first contact of the patient is with the physician, it has been natural for him to consider the patient his own property, forgetting that dealing with the sick cannot remain a personal relation, but must include other remedial agencies. Unfortunately for cooperative effort, one still encounters on all sides the individualistic attitude of physicians toward patients, but the time is at hand when the patient must be regarded as the charge of the whole profession, the ward of the hospital, the joint responsibility of all, and not merely one man's patient.

The intensely individual physician is usually the one who talks about "standardizing the hospital" and in this connection it is pertinent to say

*Address delivered before the Fifth Annual Meeting of the Ohio Hospital Association, Cleveland, Ohio, May, 1919

that if the medical profession seriously desires to help in the standardization of hospitals it must first standardize itself. This is an inescapable conclusion because of the following considerations:

Medical knowledge and medical science to-day are so varied, so difficult to attain with anything like a full and easy grasp, and so complex to administer with sureness and efficiency; their application calls for so much in the way of equipment and laboratory service as means of diagnosis that, no matter how tremendous his genius, no matter how many years he may have studied medicine, when serious and baffling complications arise it is so trying for one man alone to administer modern medicine in any full measure to the patient that it has become a procedure of group practice, of institutional administration of medicine to the patient and, therefore, the medical man to-day looks to the hospital, is dependent upon the hospital for his means of exercising the knowledge he has of medicine, and for dealing with those patients he used to handle as a personal problem.

Team Work Aids Standardization

It follows that the hospitals have a task the like of which has never yet confronted them. They have been burdened with debts. They have been distressed with the accumulations of troubles and functions they must perform; but it is unlikely that they have faced the thought that they were going to be charged with the task of organizing the medical profession. Yet that is just what they have to do. Discussion of these matters with medical men alone always gives the impression that they think it is their Herculean task to standardize the hospitals. They say: "If that hospital would only do thus and so, things would be all right." On the other hand, when the hospital is questioned: "Do you do this? Do you do that? Do you do the other thing?" the reply is: "Yes. We are trying hard, but we can't get the doctors to do, this, that, and the other thing." There is this constant shifting of responsibility.

The ultimate responsibility will fall on the hospital; hence the hospital must take up the burden of standardization, of causing the medical men to think alike on fundamental principles as regards what is the accepted procedure in modern, up-to-date hospitals.

There must be organization. There must be records. There must be laboratory service that gets to the patient. Who is to organize? Who is to give the records? Who is to apply the laboratory service to the patients? The doctor, of course. Can the Sisters, the nurses, the board of trustees organize and hold meetings for the dis-

cussion of what is going on in the hospital down to the details of every case? Certainly not! Only the medical men who are giving the service can do that. The hospital simply helps in this service. The physicians are the ones who have the prerogative; therefore it is for them to organize. They must scrutinize, they must judge their own work day by day, week by week, month by month. If they are not doing this, they are not doing their duty and clearly the patient is not receiving that to which he is entitled, and the hospitals must see to it that this duty is discharged.

Adequate Records Are Imperative

There can be no check on the service rendered unless adequate records are kept. Who is to keep the records? The hospital, of course, will keep them. Furnish the means? Certainly. A stenographer? Yes. A dictaphone? Yes; they will furnish anything that is necessary to do the transcribing. But out of whose head must the record come? Who must finally take the history and be responsible for it? The doctor. Why not the intern? Why, he is but a youngling yet; he is only learning how to take histories. It requires much knowledge and experience to sift out the truth from the history as given by the patient and if the history elicited by the intern is not gone over, corrected, perhaps filled in, and finally corrected by the physician in charge, it is not worth the snap of one's finger scientifically nor to the patient.

Can a young woman, can a Sister take a history? Perhaps if she is intelligent and careful she will learn just as well as an intern; but it will be worth absolutely nothing scientifically or legally unless the doctor goes over and approves it. Therefore the doctor must be responsible for the history.

He has to be responsible for the physical examination. But what about the function of the intern? The intern should make the physical examination. Nurses can be trained to do it, but the scientific finish and responsibility do not accrue until it has the confirmation of the doctor.

The laboratory tests follow the physical examination. They come from the technicians, from the laboratories, from the pathologists; but if they do not get the visé of the clinical men attending the case; if that laboratory work is not balanced up with the clinical findings, with the observation of the case and the history that has preceded, the laboratory is not worth anything finally to the patient nor to the growth of medicine.

Again, who is to make a diagnosis preceding operation or treatment? The doctor; and he

makes the diagnosis only on the basis of all that has preceded with the help of the hospital and its technical force. In case of any reasonable doubt, diagnosis before any operation or treatment should not be made until the knowledge of the staff of that hospital has been enlisted. Call in one doctor; another; a third; yes, even a twentieth doctor if that should be necessary. Why this extreme statement? Why has the individual doctor to-day no right professionally, institutionally, scientifically, nor ethically to pronounce a doubtful or a misgiving diagnosis preceding an operation, or even preceding treatment, without getting all the knowledge that might help him to be sure, and safe, and sound in that diagnosis? The answer is just this: Every human being to-day has a right, as against the whole medical profession in any locality, to the best of knowledge and skill of the entire medical profession.

This is rather a strong statement to make and may be proclaimed as somewhat radical. The people have become accustomed to trust themselves absolutely to their individual doctors. Because of inheritance of thought and action in this regard, and because of the attitude of the doctors themselves, the patient has come to think he belongs, body and soul, to the particular physician whom he happens to consult for any condition of ill health—a wrong and false attitude which must be changed. Great, basic changes have come into the practice of medicine within the last ten or twenty years. Medical practice has become a real science. It knows, or it does not know. There is no more mystery about it. Guess work no longer poses as knowledge. There is still guess work; there is still experiment; but the honest practitioner admits things as known, or not known. Such a practitioner knows whether a real, true, sure diagnosis is given or if it is tentative. When a decision cannot be reached, reputable doctors no longer claim they know, nor do they proceed on an uncertainty when honest

investigation or further consultation will clear up the diagnosis. To lie or pretend in such a case is unscientific and unethical. Present day means of disseminating medical knowledge by magazines, pamphlets, wire, should make to function through the local medical profession 100 per cent of all the knowledge of the medical profession everywhere and, in the presence of a complex condition, the patient is entitled to 100 per cent of that knowledge wherever he may be, local hospitals and doctors notwithstanding. This being true, no man has a professional right, and certainly no scientific nor ethical right, to deal alone with a patient in a hospital when there is any possibility of a doubt as to the sureness and safety of his diagnosis.

This is a new concept of medicine which enjoins upon the hospital the same obligation to every patient that enters into it as that assumed by the medical profession; it holds that the trustees, the owners, the administrators of a hospital owe to every patient that enters the hospital, by the mere fact that the patient is a

human being with a God-given right to the life and the well-being of life, as nearly 100 per cent of medical knowledge and skill as they can in reason be expected to render.

On the premises herein established the only conclusion hospital people can reach is this: the hospital is going to assume that responsibility in deepest earnestness; is going to see to it that no patient enters who does not get as nearly 100 per cent of service as can be brought about, and as fast as it can be accomplished; that the equipment of the laboratory, the service from every part of the hospital, the records, and, finally, the medical men who serve in the hospital, will be held to this high standard. The medical men will be told: "Gentlemen, we have a duty to every patient who comes in here and, if you are going to deal with patients in this hospital, you must with us assume the duty and cooperate with us in administering real, modern, complete, institu-

"MEDICAL knowledge and medical science to-day are so varied, so difficult to attain with anything like a full and easy grasp, and so complex to administer with sureness and efficiency; their application calls for so much in the way of equipment and laboratory service as means of diagnosis that, no matter how tremendous his genius, no matter how many years he may have studied medicine, when serious and baffling complications arise it is so trying for one man alone to administer modern medicine in any full measure to the patient that it has become a procedure of group practice, of institutional administration of medicine to the patient and, therefore, the medical man to-day looks to the hospital, is dependent on the hospital for his means of exercising the knowledge he has of medicine, and for dealing with those patients he used to handle as a personal problem."

tional, medical service to every patient admitted."

It matters little through which channel of the hospital organization this dictum is issued, but it must be done if hospitals accept this plain, simple basis of thought, namely, that the medical profession, the whole nursing profession, and the hospital profession, as three units, three elements, are bound to the patient to give him what he has a God-given right to. This is not so hard to accomplish. It just calls for a little common sense, cooperative thinking, and coordinated action. These things that Dr. John G. Bowman is telling throughout this continent, that the American College of Surgeons in its splendid idealism and generous devotion of money and energy is doing throughout the country, are not questions of great expenditures of money. They are calling upon the medical profession, upon the nursing profession, and upon all those who work in hospitals just to do a plain, simple, ethical duty—organize; see what the work is; criticise it frankly if it needs it; improve it month by month. Give a written contract of agreement to every patient when he leaves the hospital: "This is what we have done for you from the very moment you came into our hands. We have served you with all that modern, up-to-date medicine enables us to do, and we have cured you." Or, if the hospital group is unsuccessful and he goes to the autopsy room, it could be said to the nearest of kin: "We have done the best we could. We are sorry; but the ones surviving will benefit by the knowledge gained from the autopsy."

Prophecy of a New Growth

This thing is so plain, so simple, so unquestionable in its basic nature that there should be no difficulty whatever about it. Time will be needed and thought required; but what at first appeared to be insurmountable obstacles will almost disappear. Hospitals will have their monthly meetings; they will have their complete scientific records, their laboratory service, and all concerned will be satisfied through and through, in mind, in heart, and in conscience. All will be able to kneel down at night and say their prayers and thank God that he enabled them to live through another day in service to their fellow men. The hospitals will have another great satisfaction. They will have reformed, made of different mold, made higher, better, and nobler one of the grandest professions known. The hospitals are not to forget that they have this mission. The medical man is a splendid type, but he is intensely human. He has ambition, he has pride; he has vanity, and he is jealous, just as all are to some degree, but that will disappear

with cooperative work and proper support. He may know medicine, but sometimes he is a mere child in other matters. Whatever his personal qualities, the hospital has got to get hold of him and fit him into the organization. They may have to say to him: "You are a very fine doctor, but you are not the whole thing. We are glad to have you in this hospital, but you must not try to dominate it to the exclusion of others."

Results Gained by Reorganization

In the matter of organization, as soon as possible, the hospitals must get away from that "chief-of-staff" idea. The president of the staff should be elected from year to year. Let the doctors elect and the hospital board appoint. They will then teach the doctors something they really know but do not let themselves seriously think about, namely, that in medical science and in medical service there is no hierarchy, no aristocracy in the old sense of the word. There is no monopoly of medical knowledge and medical skill by any process except that gained by hard study, close application, and by absolutely honest and sincere administration of that knowledge. No scientist can claim to be what he is not, for science must engender the love of truth, and medical science must develop an altruism of service that is above all other service except religious service.

This standardization will make the doctors rise in stature of character. If they are petty, if they are jealous, if they won't play the game together, they must be gently told: "We have a team that can get along without you, no matter who you are or what you are. We know perfectly what the modern game of medicine is. It is just as simple as one-two-three, and if you are not going to play the game above board and with absolute frankness and generosity of character, you can't be on our team; go and join some other group."

That is all; and just as soon as the hospitals of this continent, without exception, will take that stand, the medical profession will get down on its knees and thank them for what the enforcement of these high requirements will do for them and for the science of medicine. The whole public will do the same.

Chicago's Typhoid Death Rate Lowest

Dr. John Dill Robertson, health commissioner of Chicago, claims for that city the lowest death rate from typhoid fever in the first six months of 1919, of any city in the world. Only six deaths were reported, or only one for every 200,000 persons. The purifying of the water supply by the chlorinating process and pasteurization of milk, are the two factors to which he attributes the effective control of typhoid.

THE CARE OF THE WOUNDED AMERICAN SOLDIER

A REVIEW OF THE METHODS AND POLICIES ADOPTED BY THE UNITED STATES GOVERNMENT FOR THE PHYSICAL AND OCCUPATIONAL REHABILITATION OF THE WAR'S DISABLED

AMERICAN casualties are small in number when compared to those of England, France, and Russia; but they are large in the hearts of those who held in warm affection the boys of the United States Army. It was not the number of wounded that led Uncle Sam to make such complete plans for their restoration, but it was because they were our wounded. Disabled for their country, it was their country's privilege to restore them if possible. Plans to make and keep the soldier physically fit included preventive as well as restorative measures. The sanitation of the camp, the proper handling of infectious diseases and the prevention of the spread of communicable diseases were as much stressed as the nursing and professional care of the sick.

Complete Restoration Sought

The Surgeon General of the Army announced his purpose to be the complete restoration, as far as it was possible, of every wounded or sick man in the army whose wounds or sickness were the result of his service. The medical head of the army recommended that no soldier disabled in line of duty be discharged from the army until cured, or as nearly so as the nature of his disability would admit, which was accepted as the War Department's policy. No war-imposed obligation has received greater consideration than this of caring for the health of the soldiers, and so thoroughly has it been fulfilled that many men have left the army sounder in body than before.

This physical reconstruction of men disabled in the service necessitated an organization under the direction of the War Department, which projected itself into the camps and cantonments at home and reached overseas to the very battle front. Within twelve months the number of medical men holding commissions in the army increased from 700 to 20,000.

Before General Pershing and his first fifty

The policy of the Federal Government in the care of disabled soldiers embodies a plan of saving human lives which many persons consider the most magnificent achievement of the war.

While the war continued the Medical Corps of the army sent back to duty 85 per cent of the wounded and sick in the hospitals at the front, thereby reversing the usual ratio of sickness and battle casualties. Since the war ended the Government, through such agencies as the Public Health Service and the Federal Board for Vocational Education, is doing as great a work for the disabled men in hospitals on American soil.

thousand reached France there had been organized, at the request of France and Great Britain, six base hospitals, which were at work under the direction of the American Red Cross. These hospitals eventually became a part of the regular military organization. Trained men on the battle field saved many lives and prevented many permanent disabilities by the prompt aid given the wounded, and major op-

erations were often performed by skilled surgeons whose hands kept steady under the sound of the enemy guns. It is significant that the first members of the American Expeditionary Forces to lose their lives or suffer wounds in the great war at the hands of the enemy, were not from among those who fought at the front, but were members of the medical corps, engaged in deeds of mercy at a group of base hospitals attacked by a hostile aeroplane.

Treatment of Special Diseases

Both overseas and at home the hospital facilities were very complete. A base hospital, usually with a capacity of about 1,200, was built at each of the thirty-two mobilization camps; forty-three general hospitals were established throughout the country for the reception of the wounded from overseas and for patients transferred from the various camps who required prolonged treatment. In order more efficiently to treat men with specific diseases or injuries, the War Department designated certain hospitals to be used exclusively for the care of men with these particular diseases. General Hospital No. 4, Fort Porter, N. Y., General Hospital No. 25, Fort Benjamin Harrison, Ind., and General Hospital No. 43, Hampton, Va., were used for the insane; Fort Bayard, N. M., Oteen, N. C., Otisville, N. Y., General Hospital No. 21, Denver, Colo., General Hospital No. 20,

*Specially written for MODERN MEDICINE and submitted to the Surgeon General of the Army and the Federal Board for Vocational Education before publication.

Whipple Barracks, Ariz., and General Hospital No. 42, Spartanburg, S. C., are among those where the tuberculosis are sent; Walter Reed, Washington, D. C., is for orthopedic cases, as well as general cases; "Evergreen" at Baltimore is for the blind, and the deaf are sent to Cape May, N. J.

Upon arriving in the United States, the

View of the administration building and some wards at Walter Reed General Hospital, Takoma Park, D. C.

wounded are taken first to the debarkation hospital at the ports of debarkation at Hoboken, N. J., or at Newport News. After a brief stay, during which time they are examined and their disabilities classified, they are transferred to the base hospital or convalescent center nearest their home, except in the case of those requiring special treatment, in which event they are assigned to the special hospital designated for the treatment of that particular disease.

Medical Care for Discharged Men

In spite of the excellent care and expert treatment given the soldier by the army medical department, some men are necessarily discharged not wholly restored to health and vigor. Recurrences of the old disability occur and Uncle Sam continues to recognize the obligation of healing these boys "as far as possible." The War Risk Insurance Act charges the Bureau of War Risk Insurance with the duty of furnishing "such reasonable government medical, surgical, and hospital services, and with such supplies including artificial limbs, trusses, and similar appliances, as the director may determine to be useful and reasonably necessary."

Even after beginning their vocational training some men discover their inability to carry on, and the doctor's care and advice are necessary. If these men have been discharged and are enrolled as students under the charge of the Federal Board for Vocational Education, medical treat-

ment is given them by the Government free of any expense.

This outlines the method which the Government follows in caring for sick and wounded service men. But this outline is only the bare framework upon which the comprehensive plan for the complete restoration of the soldier was constructed. For modern medical treatment goes farther than physical cure alone. Functional restoration is the great aim of the surgeon today. In order to achieve this more than ordinary medical and surgical measures are employed. Physiotherapy embracing electro-, hydro- and mechano-therapy, is being most successfully employed in the physical reconstruction of these wounded men. Stiffened joints are relaxed, weakened muscles are strengthened, and stumps are strengthened by massage and the beneficial effects of heat and light. Baths of every description are used in the treatment of septic wounds, and electrical devices aid in the search for sick or injured nerves. Perhaps the most wonderful of all is the plastic surgery by means of which faces marred beyond recognition of even those most loving, are remade into the familiar likeness.

Government Supplies Artificial Limbs

The number of amputation cases has been far less than might have been expected. But for the hundreds of men who need an artificial leg and the thousands who must have some substitute for the lost arm, artificial appliances become of great importance. These are not only furnished by the Government through the Bureau of War Risk Insurance but necessary repairs are made whenever required.

The Government does not consider that physical treatment alone fully meets its obligations to disabled men. The mental attitude of a sick man is such a very important factor in his recovery that special provision was made for curative work in the program of the soldier's restoration. Medical treatment was made compulsory for the wounded or sick soldier, but the choice of curative work was left to his own discretion. Work always brings more beneficial results, whether these results are to be curative or remunerative, when undertaken in a spirit of willingness, rather than by compulsion. The soldiers have chosen wisely, and occupational therapy has become firmly established as a very essential part of every army reconstruction hospital. Both psychologically and mechanically these work shops have proved valuable in the functional restoration of the wounded.

Before the armistice was signed in November last, the principal thought of the army or navy

surgeon in treating the wounded, was the possibility of his return to duty. If the soldier was too seriously wounded to be send back to the front he was held for some limited service. Eighty-five and five-tenths per cent of the wounded were able to be used in some way. But now that the time for peace is here, and the pressing need for men no longer exists, the government continues to give to our wounded and sick boys the same skilled medical care.

On March 3, 1919, Congress passed a bill authorizing the Secretary of the Treasury to provide hospital and sanatorium treatment for discharged sick and disabled soldiers, sailors, and marines, who are beneficiaries of the Bureau of War Risk Insurance. These hospitals are to be under the direction of the Public Health Service. Many of the army hospitals no longer required for men in active service, are being transferred to the Bureau of the Public Health Service.

No necessary step in the way back to health and vigor was overlooked in planning for the thorough restoration of our boys. From the moment the stretcher bearers lifted him from the field until he gains sufficient strength to firmly establish himself as a contributing unit in the economic life of the community, Uncle Sam guards the health of his soldiers, sailors, and marines. The ambulance companies, the field hospitals, the base hospitals, the hospital trains and ships were but evidences that the government's watchfulness of the sick soldier never flagged for a moment.

As zealously as America went to work to win the war, so now every energy is being bent towards bringing back to healthful usefulness those who made possible the great victory.

A brief reference was made earlier in this article to the work of the Federal Board for Vocational Education. This Board is charged with the duty of providing vocational training for all men disabled while in the military or naval forces of the United States who suffer a handicap

which will prevent them carrying on their former occupation, or some other one, without suitable training. The Board is also charged with the duty of assisting disabled men to find suitable positions after their medical care, or vocational training, or both, are complete. Every disabled man is interviewed and given the best of advice as to some new occupation if he is unable to return to his former occupation because of his service disability. During his course of training, a disabled man receives an allowance for the maintenance of himself and his dependents. The

Government, through the Federal Board, also pays all the costs of his tuition, books, materials, and incidental school expenses.

These things are provided by the Government, not as a reward, but as a simple measure of justice to those who have suffered a disability in the Nation's service. It is alike a measure of justice to the disabled man and of security and economic value to the community, that the Nation shall so manage its work for the disabled from the war that they shall come out of it morally and socially improved,—able once more to take their places in the community as useful and, therefore, happy citizens.

The new health administration law of Ohio provides for all-time health officers and nurses in districts corresponding to counties and large cities, and further provides that all medical work for the indigent shall be done by the health departments.

REEDUCATION

SURELY 'tis something Godlike to receive
These souls fresh born and fresh baptized with fire
And start them safely on a surer path,
Bewildered, some, the world has been too wild
For quick adjustment—and for these the hand
Stretched out in loving kindness is God's boon.
Some have been stunted in the far-off past—
Far-off, though still a year away, maybe,
Since time may not be measured by its hours,
But by its high emotions. These have served
At tasks unlored, and now a hope has come—
A hope to dazzling to be quite believed,
Hope of a dream, a boyish dream, come true.
The artist soul, chained to a desk; the youth
Who loves all outdoor things, the smell of soil,
The growing things he fain would help to grow;
The student torn from books ere he was grown,
To earn the needed wage—to these a hope
Dawns like a light in places underground.
And with the hope's fruition comes the thoughts
"My country loves me!" Like a gracious warmth
It fills the lonely soul, and nevermore
Will fade the glow.
Thus, surely, will arise
A newer patriotism, of the heart, not head—
A deeper, surer devotion to the land
That by adoption or by birth is his.
Justice and pity mingle, as in Him,
And in the lad a fine sweet thing is born,
A finer love for country and for God.
Yes, it is something Godlike to do this.

—ALMON HENSLEY.—THE VOCATIONAL SUMMARY.

HOW THE CURATIVE AND VOCATIONAL TRAINING OF THE WOUNDED AMERICAN SOLDIER ARE COMBINED IN THE WORK OF REHABILITATION

Fig. 1. This patient with his arm strapped down is undergoing no more terrible operation than having measured the extension-flexion of his joints and fingers in the psychological laboratory. Curative and educational work will be assigned to him on this scientific basis.

Fig. 3 (below). Light work in plastic modeling compositions and clay has some times decorative and artistic value as well as therapeutic. Perhaps an injured hand will lead some man to the discovery of an unsuspected talent; neither of these two men had ever handled any of the instruments before.

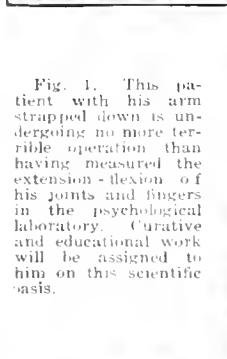

Fig. 2. Carving wooden handles is excellent light curative work for the left arm and hand, but that is not its only claim to interest, as the absorbed expression of the soldier seems to indicate. The results are mounted to the left.

Fig. 6 (below). Tools for the disabled. Note the use of dental modeling wax, which is easily molded and attached to the hand with the application of warm water to the wax, and the special appliances and tools for arm amputation cases.

Fig. 4. This model aeroplane is the completed work of some light therapeutic occupation undertaken in the well-equipped machine shop, where disabled hands achieve wonderful results—the most wonderful in some cases being their own cure. For those not mechanically inclined, ring-weaving or fine jewelry work may furnish the same means of cure and satisfy the same creative instinct.

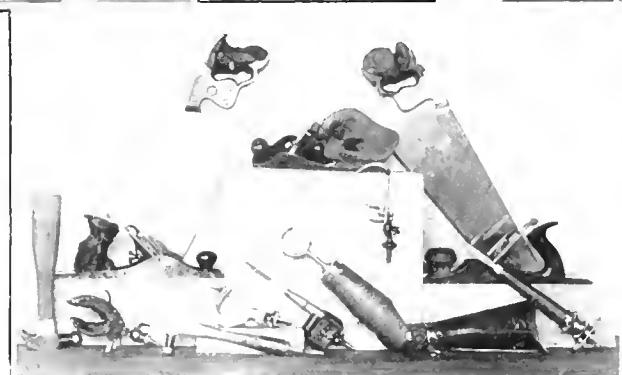

Fig. 5. Just beginning a project in the workshop, which may result in a small but perfect aeroplane like the other man has made or in any of the other contrivances which occupy minds and loosen stiffened fingers. The soldiers who return from here take home trophies of which they are almost as proud as of the German helmets they brought back from "over there."

HOW UNCLE SAM HAS PROVIDED FOR BLIND SOLDIERS—THEY LEARN TO READ AND WRITE, AND TO WORK AND PLAY AGAIN

Fig. 1. Evergreen General Hospital, Baltimore, Md., where blinded and disabled American soldiers are restored to health and retrained for vocations in which they may become self supporting. They are taught to read and to write and they learn new ways to work and new ways to play. Every man learns to use the typewriter and to write Braille.

Fig. 3. On the extensive lawns of this recreation field all kinds of outdoor sports may be enjoyed by the blind. The men are taught that systematic exercise is just as essential for them as for those who see.

Fig. 2. Headquarters of the Red Cross activities for the blind. The Federal Board for Vocational Education, working in cooperation with the Red Cross Institute for the Blind, refits the handicapped soldier physically and mentally for the years to come. A corps of industrial teachers and vocational educators instruct the soldiers in various occupations.

Fig. 4. Library and reading room. Through the agency of Braille the blind have recourse to many books which are supplied in the Red Cross Institute Building. The "Cheer-up" volumes in which are found extracts from current literature are much appreciated.

Fig. 5. One of the airy restful wards where the men can feel the sunshine. Blind men are keenly susceptible to the charm of their surroundings, which is as quickly perceptible to their quickened senses as to the eyes of other men, a fact never lost sight of at Evergreen.

Fig. 6. Bowling is one of the favorite sports of the blind patients at Evergreen. The excellent therapeutic qualities of bowling in the rebuilding of shattered bodies has placed this sport among the first on the list of those found useful in the rehabilitation of war victims. The blind soldier improves his sense of direction in the approach. He learns better to judge the distance at which sound is heard by noting the interval between the instant his hand releases the bowl and the instant it strikes the pins. Sometimes the bowl goes off into the gutter, but with practice these blind bowlers become experts.

Fig. 7. The entrance hall of the Evergreen Hospital serves also as a lounging room. It is the gathering place where the fellows spend a social hour together, and may read or write letters. In the background of the picture is a soldier with darkened spectacles playing a phonograph, while others chat or listen to the music. The association that patients have with one another in social diversions is one of the main elements in keeping up their morale, which is so important to their recovery. The blind man's attitude toward his misfortune and toward his companions, largely determines his success in later life.

Fig. 8. Through the lovely gardens of Evergreen the men delight to take their friends. This is the Elizabethan garden. The beauty of the place is important in winning the confidence of the soldier's family who sometimes hate to leave him in stranger's care.

BLINDED SOLDIERS BECOME SELF-SUPPORTING BEFORE GOING BACK TO CIVIL PURSUITS—THE PICTURES TELL HOW THEY LEARN TO BE BLIND

Fig. 9. Operating a small switchboard is one means of livelihood open to the blind which men at Evergreen are taking up. This method has already been tried out with success in civilian life among the blind and partially blind, and promises to be a popular occupation. A quick mind and more than ordinary keenness of hearing and touch are prerequisites for the blind student of switchboard operation. The exercise of several faculties simultaneously, the necessity for concentrating the attention on the switchboard for continuous periods of time, and the ability to think and act quickly, all enter into the work of the operator, who, to be successful, must possess steady nerves and quick wits. Unless the patient has these faculties well developed, he is advised against attempting this work.

Fig. 10. Carpenters' tools teach the men much about the usefulness of their hands, and, though none of them may expect actually to become carpenters, the training in the management of their fingers, and the use of instruments which they receive will be invaluable. This form of training, which develops skill in the use of one's hands and fingers as it does, is of fundamental importance in the preparation for more elaborate

tasks in the occupational courses which is to fit the patient for a new vocation. The industrial teachers study the motions that enter into each separate operation of the hands or other muscles and utilize the knowledge thus gained in correcting wrong movements or unnecessary movements which most patients perform in learning. The teachers study each movement with the aid of moving pictures, by the use of which time-studies are made.

Fig. 12. Swimming Pool at Evergreen Hospital. Being blind is not always the misfortune it seems, especially when one can follow a sport like swimming, which may be a hobby of the blind person as well as the normal-sighted person. Indulging in the manly art of swimming and similar sports develops the handicapped man's confidence in himself more surely than months of lectures and instruction. It promotes a sense of security.

Fig. 11. (Above.) In the popular dance hall. No form of recreation is more generally enjoyed by the blind.

Fig. 14. (Below.) Puzzles for finger training and for fun.

Fig. 13. Exercise in the gymnasium keeps the patients in physical trim and develops muscular adeptness. Exercises which promote better coordination of the muscles of all parts of the body are particularly useful in the rehabilitation of the blind. The new habits which blinded men must cultivate in their daily life are easier to acquire when systematic exercise of the muscles can be carried on regularly.

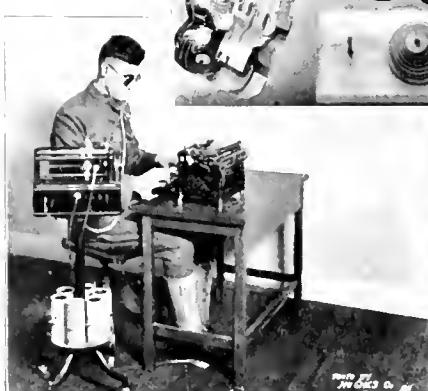

Fig. 15. Dictaphone operating useful to typewriters. It is obvious that for blind men, properly trained, the commercial world offers the most favorable opportunities, and a great deal of attention is being paid to preparing men for this line of work.

Fig. 16. Bookbinding affords valuable finger training, and it is possible that some of the men may find an opportunity to follow this occupation for a living. It has long been a favorite means of occupying the blind who frequently become very proficient.

CONSTITUTIONAL FOUNDATIONS OF FEDERAL PUBLIC HEALTH FUNCTIONS

BY FRANK J. GOODNOW, PRESIDENT, JOHNS HOPKINS UNIVERSITY, BALTIMORE, MD.

THAT the Government of the United States is a Federal Government is a commonplace not only to him who has made a study of its constitutional law but as well to the average citizen. The legal effects of the Federal character of our government are, however, not altogether clear even to the lawyer, much less to him who has not been initiated into the mysteries of our constitutional law. The Constitution contains so many general clauses that resort must continuously be had to the courts for interpretation and construction, with the result that the exact and precise meaning of many constitutional provisions can be ascertained only by an examination of a long list of decisions. Where no decisions have been made on a particular point, we must reach our conclusions as the result of argument based on decisions made with regard to other points.

There are, however, certain general principles of construction, a knowledge of which will be of great assistance in enabling us to reach a determination as to the extent of power possessed by the national government and is absolutely necessary to the answer of the question which has been chosen for discussion to-day.

Probably the two most important of these principles are:

First, That the national government may, under the Constitution, exercise only those powers which have been clearly granted to it by that instrument; and

Second, That where the Constitution thus clearly grants a power to the national government in the exercise of such a power is binding upon the states and upon the people of the United States even in case there may be a conflict between a national law and a state law.

A keener realization that insanitary places, epidemics, and preventable diseases, are matters no longer of merely local concern should have the effect of causing a broader interpretation of powers for the enforcement of public health measures.

But whatever may be the outcome of the future, for the present it is safer to base such health powers as the Federal Government may possess upon either its powers over commerce or its taxing powers.

As matters of national interest assume greater importance, it follows that the powers of the Government will increase to suit the changes in our national life.

To state these principles in another way it may be said that the national government is a government of enumerated powers, the presumption, where no mention of a power in the national government is made, being in favor of the power of the states, but state law must give way to national law in the case of all matters as to which the national government is competent and has taken action.

The national government, although of enumerated powers, is supreme in the exercise of the powers enumerated.

If now we examine the Constitution with the purpose of finding in the enumeration of powers granted to the national government the mention of any power over the public health we shall discover that no such power has been expressly granted. We shall find, however, one clause granting the power to make all laws necessary and proper for carrying into execution any of the powers vested by the Constitution in the Government of the United States or in any department or officer thereof.

General Provisions of Constitutions

We must, therefore, examine some of the general clauses of the Constitution with the purpose of ascertaining whether any of these when combined with the power to make all laws necessary and proper for carrying into execution the powers granted are or may be construed as granting to the national government powers relative to the public health.

The most important of these general clauses from the point of view of to-day's discussion is unquestionably the power to regulate commerce with foreign nations and among the several states. It is to be noted that the Constitution neither defines nor describes "commerce," nor states what is the meaning of the words "regulate" and "among the several states."

*Read before the Conference of State and Provincial Boards of Health, June 7, 1919, at Atlantic City, N. J., and published simultaneously in MODERN MEDICINE and the American Journal of Public Health.

At first, governed by the particularistic states' rights ideas of the time, which were justified in large measure by the existing economic conditions, both Congress and the Supreme Court took a rather narrow view of the extent of this power. Thus when it came to be regarded about 1820 as necessary that the central government should make some provision for means of communication between the eastern states and the new states which had been established west of the Alleghany Mountains and in the Mississippi Valley, it was believed that the only authority possessed by Congress was to build roads, which after they were built should be handed over to the states. The states alone, it was thought, might administer them and care for their maintenance and repair.

Federal Powers Over Commerce

The gradual centralization of economic conditions, which has been characteristic of American development, has, however, caused the adoption, at the present time, of a much more extended conception of national power under the Constitution. Thus the meaning of the word "commerce" has been greatly enlarged. Commerce as a subject of congressional regulation embraces at the present time, in the first place, transportation by both land and water and the means and instrumentalities of transportation. Commerce, *i. e.*, the thing which under the Constitution may be regulated by Congress, therefore includes not merely the act of transporting persons or things from one place to another, but as well both artificial land and water routes and their terminals such as harbors, the vehicles by which the act of transportation is performed, and the persons, both carriers, shippers and consignees on the one hand, and employers and employed on the other, who are engaged in the act of transportation.

In the second place, commerce embraces purchases and sales and the negotiations entered into in order to lead to sales of all articles ordinarily made the subject of trade, as well as agreements for such purchases and sales, made both between the purchasers among themselves, and the sellers among themselves, on the one hand, and between the purchasers and sellers with each other on the other.

Trade Relationships and Manufacture

In other words commerce in the constitutional sense includes on the one hand the physical instrumentalities by which commerce is carried on and on the other the transactions on which trade relationships are based.

Finally, while commerce does not include manu-

facturing, the tendency is to regard manufacturing as a part of commerce where its regulation is necessary to the effective regulation of what is admittedly commerce.

All of these things, operations, and processes are regarded as within the regulatory power of Congress, provided they can be regarded as a part of commerce "with foreign nations" or "among the several states." Commerce of such a character is held to be that which originates in one state and terminates in another, as well as commerce which originates and terminates in the same state, provided the regulation of such commerce is necessary to the effective regulation by Congress of what is recognized as commerce with foreign nations or among the several states.

The word regulate is given an equally wide meaning. Thus it is held that the power to regulate commerce includes the powers:

First. To construct, or provide, by the chartering of companies, for the construction of routes by land or water over which commerce with foreign nations among the several states is possible, and to lay down the rules to be observed by those making use of such routes.

Second. The power to regulate includes the power to determine the private legal relations which shall exist among those persons engaged in the commerce subject to regulation, so far as those legal relations may affect the carrying on of commerce. Thus Congress may regulate the contracts and liabilities between shippers and carriers, between carriers and their employees, between sellers and between purchasers, and between sellers and purchasers.

Control by Power of License

Finally, the power to regulate includes the power to prohibit commerce in certain articles and certain methods of carrying on commerce and to license those engaged in commerce.

The enormous extension which has been given to the power of Congress to regulate the commerce among the several states is causing the old distinction between a commerce among the several states which is subject to Congressional regulation and commerce within the limits of a single state which is subject to state regulation, almost to disappear and to subject all commerce to the power of Congress. This distinction has disappeared with regard to commerce carried on by water, which is spoken of as navigation.

The power of the national government to regulate commerce may be exercised, it will be noticed, not merely with the idea of promoting commerce from an economic point of view but as well as

with the idea of limiting commerce in order to protect the public health or safety. It includes, therefore, the power to establish quarantines and to deny the right of entry into the country or of transportation from one state to another to objects or persons where that entry or that transportation may, in the opinion of the competent authorities of the national government, endanger the public safety.

The health powers which Congress possesses under the commerce clause are as a matter of fact both because of actual conditions and also probably owing to our constitutional theory larger in the case of foreign commerce than in that of commerce among the several states. At any rate, it is certain that in the case of foreign commerce the same perplexing questions which present themselves in the case of commerce among the several states do not arise. In the case of foreign commerce the only action the national government can, in the nature of things, attempt to take is action in the nature of an embargo or an inspection. There is no question that it may do either of these things.

Matters Under State Jurisdiction

In the case of commerce among the several states, however, conditions are different. Congress may, it is true, deny to almost anything it sees fit the right to be an article of interstate commerce, and may punish those who, contrary to the law, ship the prohibited article from one state to another. But it is incompetent to prohibit either the manufacture or the use within a state of an article however harmful since these are matters within the jurisdiction of the states and not in that of the national government. All the United States government can do as a direct result of its commerce powers is to prohibit, under criminal penalties, the interstate transportation of articles.

Generally speaking, interstate or foreign transportation does not begin until the articles start on their journey. Any action which precedes transportation has to do with manufacture rather than with commerce and is, therefore, not within the competence of the national government except in so far as its regulation may be necessary and proper for the effective exercise of the power to regulate commerce. Transportation, furthermore, ceases when the articles have reached their destination and have either been taken out of the original package in which they were shipped or have left the hands of the person who brought them into the state, *i. e.*, the consignee. Congress may not regulate or prohibit their use after they have thus fallen under the power of the state.

The United States government may, however, as has been said, provide for the criminal punishment on the one hand of him who makes the prohibited shipment and on the other hand of the consignee who sells the prohibited article before the original package is broken. To exercise this power, however, it must have the means of determining whether the article transported falls within the prohibited class. It thus may provide for the labelling of the articles transported and for the inspection at the place of manufacture of articles intended for interstate transportation as well as for the licensing of the persons engaged in their manufacture. The United States government has not, it is true, either inspection or licensing powers to the exercise of which manufacturers of articles destined for consumption within the state of manufacture must submit, but it has the power to deny to articles not inspected and not made by licensed manufacturers the right of interstate transportation.

Food Law and Child Labor Act

Probably the two most notable attempts of the national government to regulate commerce among the several states in the interest of the public health are the Pure Food and Drugs Act, and the Child Labor Act. The first, which forbade the transportation from one state to another of adulterated food products and drugs was upheld by the Supreme Court as a constitutional exercise of legislative power. The second forbade the transportation in commerce, among the several states, of goods made in factories in which children under fourteen were employed or in which children under sixteen were employed more than eight hours a day. This act was, by a divided court, held unconstitutional because it was regarded as an attempt to regulate the methods of manufacture within a state which were a matter for state and not for national regulation. The harm to health, which resulted from the manufacture of articles made by child labor, is done in the state of manufacture. The transportation of such articles cannot, in the nature of things, be harmful. The damage done is thus due to manufacture and not to commerce.

We must, therefore, conclude that the health powers of Congress to be derived from the Commerce Clause of the Constitution relate for the most part to the act of transportation as it has been defined by the decisions. Whether this will always be the rule is open to come question. For in other directions, of which decisions under the Anti-Trust Act are examples, actions which related to manufacture rather than to transporta-

tion have been held to come under the regulating power of Congress. On the theory that they were prohibited by the Anti-Trust Act combinations both of employers and employed with regard to manufacturing and sales within a state rather than transportation have been punished as illegal.

Taxing Power and Its Principle

The second great source of national power with regard to the public health is to be found in the power granted by the Constitution to Congress to "lay and collect taxes, duties, imposts, and excises, to pay the debts and provide for the common defense and general welfare of the United States."

The powers derived by Congress from this clause of the Constitution are of two kinds. They are in the first place repressive and in the second place they are powers of positively promoting the public welfare.

In the first place Congress may, in the exercise of its taxing powers, impose on any occupation or any article which is deemed to be harmful a tax of a prohibitive character, for, as the Supreme Court has on more than one occasion said, "the power to tax is the power to destroy." An instance of the exercise of the taxing power by Congress with the purpose of making impossible the production of the article taxed is the law taxing phosphorus matches. An example more recent of this method of protecting the public health is the provision in the last revenue bill imposing what amounts to a prohibitive tax on all manufacturers employing child labor.

Public Health and Taxing Power

It will be noticed that the powers relating to the public health, which may be derived from the taxing power of Congress, are in some respects broader than those which find their origin in the commerce power. Under the former, methods of manufacturing within the states may for all practical purposes be prohibited, although Congress has no direct power of prohibition. Such a method of protecting the public health naturally lends itself to matters where prohibition rather than regulation is sought. But it may perhaps be suggested that this method of prohibition permits of the accomplishment of a good deal to which at first blush it may not seem to be adapted. Thus, what is to prevent the imposition by Congress of prohibitive taxes on all manufacturers who do not provide safety appliances for the protection of their workers or who do not secure sanitary conditions under which work may be carried on? The only answer to this question is that, while the limitations on the taxing power of

Congress are few in number and rather ineffective in character, it has usually been considered that the classification of articles and persons for taxation must have some reasonable relation to the object sought. It may well be that either because such a classification would be regarded as improper or because the attempt to exercise the taxing power in this way would be regarded as a palpable evasion of the Constitution and an encroachment upon the rights of the states, such laws as have been suggested would be held to be unconstitutional. The result of the litigation, which will unquestionably follow the attempt to impose special taxes on manufacturers employing child labor, will, doubtless, throw much light on this up-to-now unsettled question.

The Harrison Narcotic Law

Another example of the use by the United States Government of its taxing power in the interest of the public health is to be found in the so-called Harrison Act relative to the sale of certain drugs. The purpose of this act is not so much prohibition as regulation. It is an interesting example, further, of an attempt to secure through the exercise of the taxing power information as to the users of drugs which is available for use by the officers of the states charged with the enforcement of laws regulating the use and sale of drugs. It may not be said that the use of the taxing power for this purpose is clearly constitutional.

But Congress may use its taxing powers not so much to destroy as to promote directly the public welfare. That is, it may appropriate the money derived from the collection of taxes for helping the states solve their sanitary problems. It may establish, as it has established, a national public health service which may be authorized to cooperate with and assist the health authorities in the states. It may establish hospitals and sanitariums provided it secures the consent of the states in which they may be situated. It may make grants to the states in aid of their health administration and may make such grants subject to the condition that the states maintain certain standards and submit to inspection.

But while the United States government may thus exercise through its power of appropriating money, a profound influence on state public health administrations and through them on the public health of the country generally, it may not of its own accord and without the consent of the states concerned step in to interfere with the sanitary work of the states.

In what has so far been said what has been borne in mind has been for the most part the

power which the United States government possesses with regard to matters usually regarded as reserved by the Constitution for the states. It must, however, be remembered that the United States government has powers exclusively its own, such as its powers in the District of Columbia, the territories and the United States reservations. Here its power is unlimited by any consideration of states rights. Furthermore, in time of war its powers to raise and support armies, to provide and maintain a navy, and to declare war are construed to carry with them the power to do, even within state lines, what is necessary to protect the health of its soldiers and sailors. We have recently had notable instances of the exercises of such powers. But fortunately a state of war is not a normal condition, and while the health powers of the United States government at such a time are very important still they are infrequently exercised and consequently have little permanent influence.

A word also should be said as to the possibility of the exercise of health powers by the United States government as a result of its exercise of its treaty-making power. It is unquestionably true that Congress may exercise legislative power to carry out the provisions of a treaty which it would not possess had the treaty not been made. We have had, however, few instances of the exercise of such powers and fewer still decisions upon their propriety. It would, therefore, be unwise to base any large health powers upon so uncertain a foundation. But, it is well to remember that the tendencies nowadays are centripetal in character and that, with the increasing economic unity of the world, much may in the future be desirable which in the past would have seemed almost outside of even the realm of speculation.

But whatever may be the outcome of the future, for the present it is safer to base such health powers as the United States government may possess upon either its commerce or its taxing powers, and there is little doubt that, with the increasing feeling that our national interests are growing in importance with the improvement in the means of communication, the powers of the United States government will increase to suit the changes in our national life.

Insanitary conditions, as a matter of fact, are no longer of merely local concern. Epidemics are not respecters of state or even national lines. A keener realization of this fact will unquestionably have the effect of causing a broader interpretation of existing powers and may well result in constitutional amendment where such broader interpretation is not possible.

DR. ABRAHAM JACOBI—IN MEMORIUM

Abraham Jacobi, 1830-1919.

The career of Dr. Abraham Jacobi is ended, at the age of 88 years, but the fruits of those professional studies and endeavors to which his life was devoted remain as permanent benefits to the public which he served, and the profession which honored him in life and still honors him in death.

His sudden death July 10, at Lake George, N. Y., where he had his summer home, deprived the American medical profession of one of its most noted men.

Dr. Jacobi was born at Hartum, Westphalia, Germany, May 6, 1830. He studied at three German universities, Griefswald, Göttingen, and Bonn. He was graduated from the University of Bonn in 1851. While a student he was identified with the German revolutionary movement in 1848. In connection with his activities he was imprisoned for two years. He escaped from imprisonment and came to America.

From 1860 to 1864 he held the professorship of diseases of children at the New York Medical College, and in 1864 he accepted a similar position with the University of New York. He became professor of pediatrics in the College of Physicians and Surgeons in 1870, a position which he held for twelve years.

Nearly every honor which the medical profession could bestow upon one man in a lifetime were his. He was twice president of the American Pediatric Society and the first chairman of the Section on Diseases of Children of the American Medical Association. He was president of the Association of American Physicians in 1896; of the New York State Medical Society in 1882; of the New York Academy of Medicine from 1885 to 1889.

His principal contributions to the literature of medicine are contained in the *Collectanea Jacobi*, in which are assembled address and monographs which, in some instances, attracted unusual attention.

PROPER RELATION OF FEDERAL AND STATE GOVERNMENTS IN PUBLIC HEALTH WORK

BY ALLAN J. McLAUGHLIN, M.D., ASSISTANT SURGEON GENERAL, UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.*

THE ideal relation between Federal and state governments in public health work should be such as to insure the covering of the entire field of public health between them. All gaps should be covered by one or the other jurisdiction, and in twilight zones there should be the most complete understanding of a frank policy which would preclude overlapping duplication or conflict.

If, under such a policy, the Federal Public Health Service did work which the state should do but was unable to do, the Federal Health Service would be acting presumably under its authority to assist states, and its activities should not continue beyond the time when the state officials were able and willing to take over the work.

In order to consider the proper relation between Federal and state public health agencies, it is necessary to review briefly the powers and functions of the United States Public Health Service and the authority therefor.

The functions of the United States Public Health Service may be considered under the following heads:

1. Police.
2. Investigative.
3. Demonstrative.
4. Coordinative.

Police power has been given very sparingly to Federal health authorities and delegated by states in large measure to local authorities because the ultimate application of police power to the individual citizen logically belongs to the agency with which he is in direct contact, viz., the local board of health.

It is clear that police power not specifically given by the Constitution to Federal agencies is reserved to the states or to the people. There is also police power implied but not expressed in

To secure the maximum of improvement in national health, nation-wide programs must be devised for each problem with which public health officers are confronted.

The Federal health service devises such programs on the basis of its information on disease prevalence.

The success of such work lies in the development and utilization in every state of strong divisions for the control of communicable disease, and in cooperation with local agencies of specially trained men from the Federal service who keep all such measures up to uniform standards.

the Constitution inherent in the Federal government in connection with the general welfare and interstate commerce clauses. This power is necessary to cover conditions not amenable to or corrigible by state police power and its exercise cannot be a usurpation of state authority.

Congress has repeatedly given police power by statute to Federal agencies to cover such conditions but has always maintained the attitude that in health matters the state and local agencies should be utilized to the limit of their legitimate fields.

The Quarantine Law of 1890 gives very definite powers to the Federal health authorities to prevent the introduction of cholera, yellow fever, smallpox or plague from one state to another without reference to utilization of state machinery, and provides for the promulgation of rules and regulations with penalties for infraction thereof.

The Quarantine Law of 1893, which includes all communicable diseases, provides that the Public Health Service shall cooperate and aid state and municipal health boards in the execution and enforcement of state laws and regulations and of Federal laws and regulations. It provides that where no state or local regulations exist or where these are insufficient, the Secretary of the Treasury shall make such additional rules and regulations as are necessary to prevent interstate spread of such diseases.

It provides, further, that the rules and regulations promulgated by the Secretary shall be enforced by state and local authorities where they will undertake to execute and enforce them, but if state or municipal health authorities fail or refuse to enforce said rules and regulations, the

*Read before the Conference of State and Provincial Boards of Health, June 7, 1919, at Atlantic City, N. J., and published simultaneously in MODERN MEDICINE and the American Journal of Public Health.

President shall execute and enforce the same and adopt such measures as in his judgment shall be necessary.

In order to carry out this policy of utilizing state and local health machinery in the prevention of the spread of disease, Congress has repeatedly appropriated large sums "to aid state or local boards or otherwise in preventing and suppressing communicable disease" (Epidemic Fund).

Congress annually appropriates for the Interstate Quarantine Service sums of money from \$15,000 to \$1,500,000 for cooperation with state and municipal health authorities in the prevention of the spread of disease in interstate traffic.

The question of delimiting the police powers of Federal and state authorities is an academic one—and for practical purposes satisfactory results can be secured in most sections by utilizing state power alone coordinated by the Federal Health Service in a national program.

As the state health machinery becomes more highly organized and perfected, the need of exercise of Federal police power will diminish and the need of Federal coordinative activity will increase.

The prevention of the spread of epidemic disease from one state to another, may be handled in one of two ways:

First, by the present system of awaiting the outbreak of an epidemic and then attempting its suppression.

Second, by maintaining such a close check upon disease prevalence that prompt and early information of undue prevalence is at once available, and suppressive measures taken before actual epidemic proportions are reached.

It is manifest, therefore, that the policy of the United States Public Health Service should be to develop state health departments and especially those divisions in a state health department whose effective operation in the interest of the state itself tends to prevent the spread of disease from one state to another.

The most effective means of preventing interstate spread of disease at the disposal of the Federal government to-day lies in the development and utilization in every state department of health of strong divisions for control of communicable diseases, water, and sewage.

To develop these divisions and bring them to a standard of uniform excellence it is necessary to detail trained men from the Public Health Service to assist the state health officers. In many states these divisions (usually called divisions of communicable disease and divisions of sanitary engi-

neering) do not exist or exist in name only. In states which possess such divisions plain justice suggests that the Federal Government should render some assistance in doing work which is called for by Federal law and regulation.

Investigative Functions

The investigative function of the Public Health Service has no limit other than the amount of money which may be appropriated by Congress.

The Act of 1912 authorized the service to study and investigate the diseases of man and conditions influencing the propagation and spread thereof, including sanitation and sewage, and the pollution directly or indirectly of the navigable streams and lakes of the United States.

Under this very broad authority, investigation of any phase of public health work may be undertaken. The Act further provides for the publication of information for the use of the public.

Sufficient funds should be secured from Congress to undertake and carry on such research as is necessary in order to furnish to the health officer in the field diagnostic, prophylactic and curative weapons for the suppression of communicable disease.

The economic advantage of doing this in one hygienic laboratory rather than in forty-eight is at once apparent.

Demonstrative Functions

The work done under the investigative authority of the Act of 1912, especially the field work, is nearly always demonstrative and can be utilized as public health demonstrations of all kinds.

In addition Congress has given specific authority for demonstrations in rural sanitation contingent upon partial support by state or local agencies.

Nothing compares in effectiveness with an actual demonstration of how work should be done in the individual communities. Here again the United States Public Health Service is limited only by the amount of money appropriated by Congress.

Coordinative Functions

The coordinative function of the Public Health Service in achieving national success against any public health problem is perhaps the most important function which the service exercises. Some Federal coordinating agency is necessary in order to secure a synchronous attack upon any disease, with uniformity of method over the entire area of the United States. To secure the

maximum of improvement in our national health we must have nation-wide programs for each problem with which health officers are confronted.

The example of our Venereal Disease Campaign serves to show what may be accomplished in other fields by the same methods.

The coordinative function of the Federal Public Health Service is but the national demonstration of what is exercised by state and local health authorities over smaller areas.

In other words, public health organization—Federal, state and local—should have the following relationship:

SUPERVISORY AND COORDINATING AUTHORITY	WORKING UNITS TO BE COORDINATED
U. S. Public Health Service	State Departments of Health
State Department of Health	Local Health Departments
Local Health Departments	Individual Citizens

The coordinating and supervisory authority furnishes the program in order to secure teamwork and endeavors to have this program carried out by all the units within its jurisdiction.

The Public Health Service has a detailed comprehensive nation-wide program for every public health problem, but these programs cannot be put into effect without adequate funds.

I hope I have made it clear that the only need of the Public Health Service is sufficient money to carry out its programs.

The service now possesses all the authority and

function which can be given by Congress to a Federal health agency within the limits of the Constitution.

Public health work aims at the eradication of preventable disease, the elimination of corrigible, physical and mental defects, and the maintenance of all individuals in the best possible physical and mental condition.

To achieve such aims demands a partnership with an exhibition of most perfect teamwork by Federal, state, and local officers. I have already mentioned such a partnership in the venereal disease campaign. The proposed Lever Bill for rural hygiene provides, if anything, a better example of what such a partnership should be.

There is ample precedent for this type of Federal cooperation with state and local authorities, as Congress has passed similar legislation covering good roads, vocational education, and farm demonstration work.

Let us waste no time in a futile effort to delimit accurately the police power and authority of each of these three jurisdictions, but let us leave such discussion to the academicians. As practical men let us disregard the theoretical boundaries of varying police jurisdictions and attack each health problem by joint concerted action according to a nation-wide program, remembering that the spread of disease recognizes no boundaries—local, state, or Federal.

When is there happiness in a bottle of milk? These city children are experiencing enjoyment with three straws and a bottle of milk. Part of the program of the health weeks that many cities are conducting this year is to teach the food value of milk and the need for clean milk. The mothers in crowded districts have been made to know the food value of milk by many years of effort in teaching food standards, and their children are learning the lessons in food standards from their mothers. MEDICINE AND INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

HIGH GRADE SURGICAL SERVICE, WELL ORGANIZED, CHEAPEST UNDER COMPENSATION ACTS

SOCIETY at large took a great forward stride when the system was instituted in the several states providing for the care of the injured workman at his employer's expense, wherein the employee was compensated for his lost time, whereby he was paid a definite sum for permanent disability, and where loss of life brought at least some financial assistance to the family of the workman killed in industry. In this way society made some effort to overcome the injustice of the loss of life and limb incident to production.

The operation of Workmen's Compensation Acts focussed attention upon the fearful economic loss from preventable accidents. Coincident with the establishment of the Workmen's Compensation Acts there sprang into being the "Safety First" movement,—one of the most strikingly successful educational movements of this age. While it has been often claimed that the economic pressure of the Workmen's Compensation Acts was responsible for the fruits of the safety movement, closer analysis leads one to believe that a far higher purpose than the mere financial one must have actuated the proponents of the safety movement in order to obtain such remarkable results.

Praiseworthy as has been the legislation which created the industrial commissions of the various states, much remains to be done to achieve the best results possible under the plan of furnishing surgical attention to the injured. Workmen as a class are entitled to better surgical service than they are to-day receiving on the average. In the main, medical men and not surgeons are looking after the injured. Fewer cases than so deserve are receiving hospital care. The percentage of permanently disabled is greater to-day than would be the case under a better organized surgical service directly under the control of the Compensation Commission.

Under the former plan of the self-insured and the re-insured, there existed perhaps a more definite impelling motive for a careful selection of the physicians who were to look after the risks of the various industries. The fear of bad sequelae,—ankylosed joints, malformations, permanent crippling, etc., with the attendant law-suits,—to say nothing of the undesired publicity connected therewith, brought the skilled surgeon to the injured man perhaps more frequently than at the present time. At any rate, more injury cases were sent for their first attention to hospitals, where, in most instances, they received skilled care.

With the coming of the Workmen's Compensation Acts, which allow the patients free choice of physicians the injured man most naturally turned to his family physician in the first moments of his mental and physical distress. Thoughtless employers, and especially those not intelligent enough to take part in the safety movement for their own shops, "passed the buck," as it were, to the man himself, or simply secured the nearest physician for the care of their men.

The foregoing is not offered as a criticism of the profession, the employer, the compensation commissions, or the employee; but points out the mistake naturally coincident with the institution of such a huge new social undertaking. It would seem, however, that we now have had sufficient experience and that enough time has elapsed to emphasize the necessity for definite organization of the surgical forces of the state under the industrial commissions in order to assure the workmen full justice after injury.

How inadequate our organizations to-day are for this tremendous task is perhaps best illustrated by the mechanism that exists in Ohio, said to have what is perhaps the best Workmen's Compensation Act so far enacted in any state. Yet, here in Ohio, where approximately three million dollars are paid out annually for surgical and hospital care, the surgical organization is so woefully

inadequate that it is physically impossible for the medical director even to approximate a critical review of the work done by the doctors of the state at large in connection with the surgical care of injured workmen. The salaries allowed the surgeons who supervise the work are totally inadequate, while the number of such physicians is absurdly small.

Any business spending \$3,000,000 would not hesitate to expend in the neighborhood of \$150,000 in executive salaries. For the purpose of organizing such expenditure men of the highest capacity would be secured at salaries ranging down from \$20,000. But the Industrial Commis-

sion of the state of Ohio, however, pays its chief surgeon the munificent salary of \$3,500.

Should not the legislatures, the industrial physicians, and the industrial commissions make this subject one of immediate inquiry to the end that intelligent service, organized by districts, be instituted under the various compensation acts so that the injured workmen may receive better surgical care? Such organization, in connection with more scientific rehabilitation work, will not only save life and limb, and reduce the number of the permanently disabled, but would considerably lessen the premiums now paid to cover such service.

EDITOR.

WOOD ALCOHOL POISONING

BY R. P. ALBAUGH, M.D., UPSON NUT COMPANY, CLEVELAND OHIO, FORMERLY DIRECTOR, DIVISION OF INDUSTRIAL HYGIENE, OHIO STATE DEPARTMENT OF HEALTH

WOOD alcohol is used in a great variety of industries in which it is recognized as such and, in addition, is encountered many times as an ingredient of various substances not suspected as containing wood alcohol. It is frequently used as a denaturant as well as a substitute for ethyl alcohol. It is an important industrial poison chiefly because of the ease with which it gains entrance into the body and also because of its highly toxic nature. It may be absorbed from the digestive tract, the respiratory tract, or through the skin. It is very rapidly absorbed, death having occurred when persons were subjected only a day or two to the fumes. It should be mentioned also that its introduction into beverages has been frequently reported.

Symptoms.—In acute cases there are usually headache, nausea, extreme weakness, dilated pupils, conjunctivitis, temporary blindness, slow respiration, weak and rapid heart action, cold and clammy extremities, and perhaps deep and prolonged coma ending in death from cardiac collapse. In the chronic type of cases, permanent blindness is the chief symptom. The blindness in acute cases is due to an inflammatory condition of the optic nerve and the ocular conjunctiva, whereas the permanent blindness in chronic cases is due to atrophy of the optic nerve. Inflammation of the skin of the hands and arms frequently occurs among workers exposed to the fumes or those actually handling wood alcohol.

Diagnosis.—If there is knowledge of exposure, the diagnosis should be simple; otherwise a differential diagnosis must be made from epilepsy

and from all types of coma—uremic, diabetic, cardiac, toxic, cerebral, and traumatic. The diagnostic features of the acute type of poisoning are extreme physical weakness, acute gastro-intestinal symptoms, blindness, and deep and prolonged coma. These symptoms, together with history of exposure and an alcoholic breath, are the cardinal points in diagnosis.

Treatment and Prevention.—The treatment consists essentially of ridding the body of the poison, and supportive measures. Frequent gastric and rectal lavage should be carried out early, as wood alcohol is but slowly and incompletely oxidized in the body to the more dangerous poisons, formaldehyd and formic acid. Transfusions or intravenous saline or sodium bicarbonate infusions should be administered. The patient should be kept warm and oxygen, adrenalin, caffeine, camphor, strychnin, or digitalis freely given. Prevention depends upon elimination of contact with the skin, labelling of containers, and sufficient ventilation to keep the extent of wood alcohol in the air below one part per ten thousand volumes of air.

INDUSTRIAL BOARDS' PROCEEDINGS

The proceedings of the fourth annual meeting of the International Association of Industrial Accident Boards and Commissions have been reprinted in Bulletin No. 248 of the United States Bureau of Labor Statistics, workers' insurance and compensation series. The discussions during the convention, which was held in August, 1917, were arranged under the following divisions: accident prevention; how claims are handled, with special reference to lump-sum settlements; medical aspects of compensation insurance; medical competence and hospital efficiency; accident problems; needed changes in legislation; administrative problems.

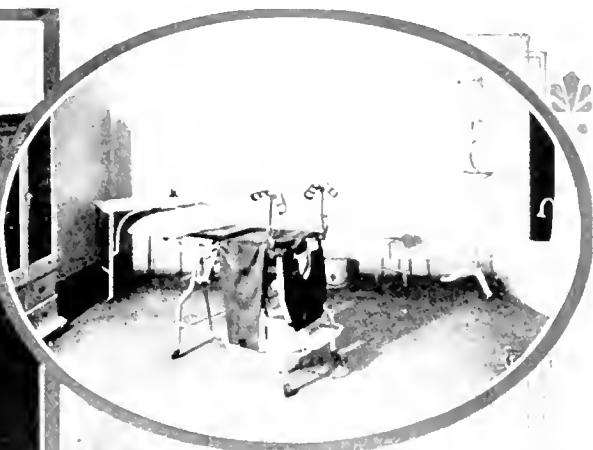

*This article is the third of a series by Dr. Albaugh on the common industrial poisons. The fourth article in the series, on "Anilin Poisoning," will be published next month.

THE SURGEON IN RELATION TO PUBLIC UTILITIES*

BY CHARLES M. HARPSTER, PH.G., M.D., F.A.C.S., TOLEDO, O.; CONSULTING CHIEF SURGEON FOR OHIO, HENRY L. DOHERTY COMPANY, NEW YORK CITY†

Consultation of the chief surgeon and staff of the Doherty Companies in Ohio. At the right are two views of the surgery at the Toledo Railways & Light Company.

Part I

THE initial account of the work of the medical department of the Toledo Railways & Light Company was made in the July, 1918, issue of the *Doherty News* in which report the institution of this service is commented upon as a logical outcome of the consistent policy of the Rail-Light Company in considering the welfare of the members of its organization.

Before the work was undertaken a thorough study of methods in vogue throughout the country was made under the direction of the general safety department at New York, the local safety agent, and the chief surgeon for the companies. As a result of these investigations a system of examination and records was designed particularly to meet the existing conditions.

It was thought best to establish the medical department directly in connection with the offices of the consulting surgeon and special facilities were installed to take care of the work. The physical examinations of the men were originally made at the medical department, but a more convenient arrangement has been found by handling all the physical examinations at the employment bureau, which is situated in connection with the general offices of the company. As an adjunct to

the plan, each plant is equipped with first-aid stations. Typical views of these stations are presented of the installation at the Acme power plant. Only one unit of this plant is completed, but as it will have ten units when finished a first-aid station adequate for the care of ten units has been provided. Paraffin paper is supplied at these stations. Its use in the case of burns and many other wounds has revolutionized the treatment of these cases, and has very materially shortened the period of disability.

The work of this corporation in protecting the health of its employees as an example of the modern trend of industrial medicine is commented upon in the *Ohio State Medical Journal* of August, 1918, and the consulting surgeon is given credit

*Dr. Harpster, in his capacity of consulting chief surgeon in Ohio for Henry L. Doherty & Company, is chief surgeon of the following Ohio public service companies: Atlas Chemical Co., Toledo; Acme Power Co., Toledo; Toledo Railways & Light Co., Toledo; Toledo, Ottawa Beach & Northern Ry Co., Toledo; Toledo & Western Railway Co., Adrian, Mich.; Maumee Valley Railway & Light Co., Toledo; Adrian Street Railway Co., Adrian, Mich.; Toledo Beach Co., Toledo; Toledo Casino Co., Toledo; W. G. Laird Co., Toledo; Industrial Heating Co., Toledo; chief surgeon, Toledo & Indiana Ry Co., Toledo, Ohio.

†A two-part article. The second installment will deal with classification and methods of handling injury cases.

for working out in Toledo a medical system that is recommended to public service utilities throughout the United States. Of the value of this work from a financial standpoint, the *Journal* says:

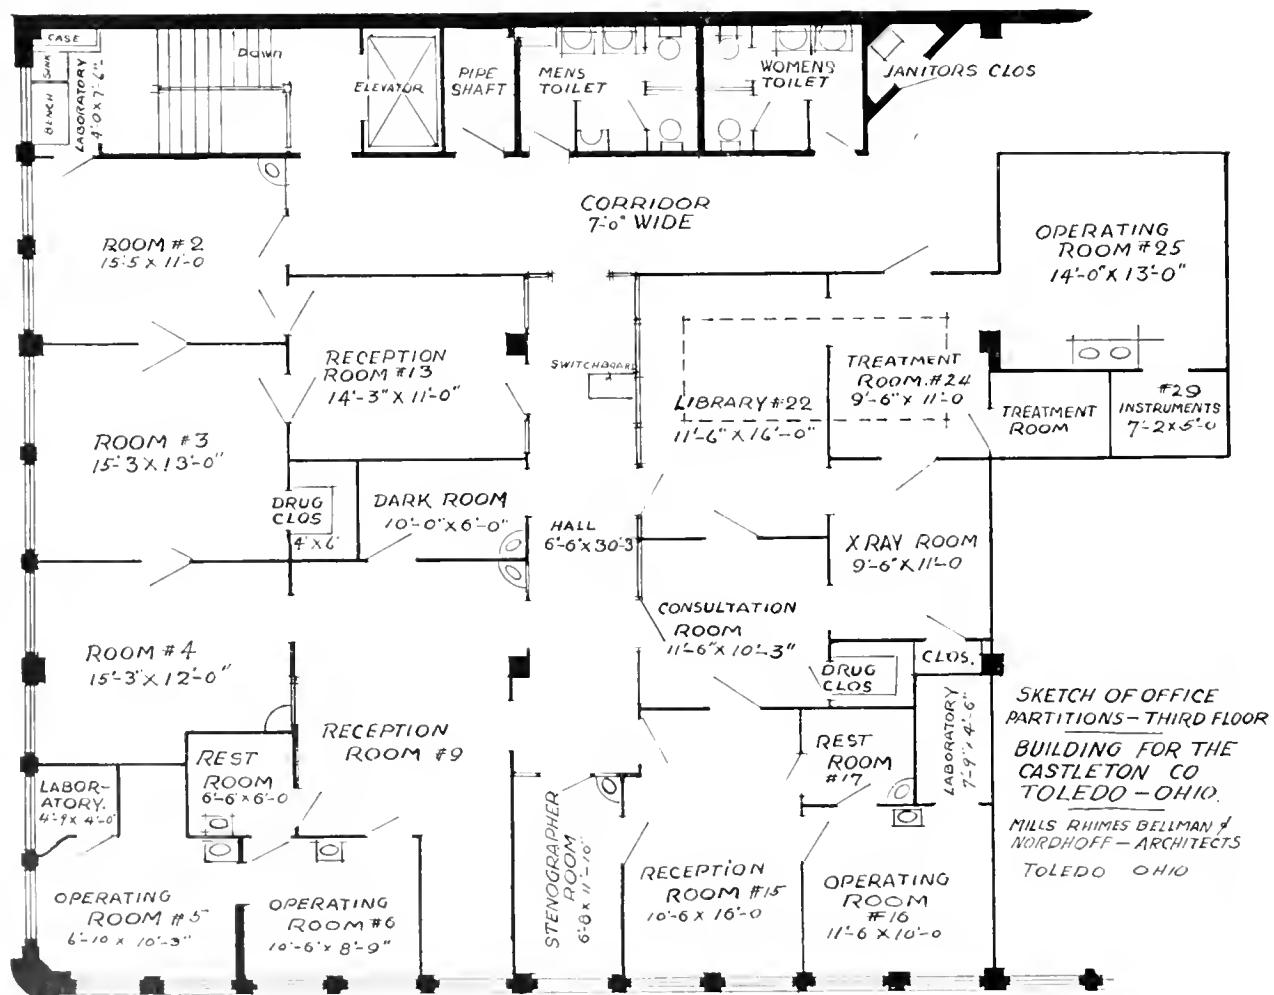

"By a reasonable expenditure in maintaining the medical department, the Toledo Railways & Light Company has secured remarkably good results in keeping up the efficiency of its men, and also in preventing the employment of those with ailments which might not be readily noted. The importance of this can be appreciated in the railway department alone, where, if a motorman is suffering from an affection of the heart or an epileptic condition not noticeable to the casual observer, he would be a hazardous employee rather than an efficient one."

The work undertaken by the medical department is the care of the injuries of the employees. Provision for first aid measures is made as close to the man's work as possible, and for the care of

routine dressings with as little loss of time for the men as possible. A convenient arrangement of first aid stations and dressing rooms encourages the men to have all minor injuries cared for, and makes it possible to follow up all cases under care. As the work became organized, the medical department was expanded so that it is now possible to handle major operations when the exigencies may demand it.

Physical Equipment

The first requisite in the care of injured people is the provision of office equipment sufficient to carry on the work. A number of views of these offices are presented. They are accessibly located. There are the reception hall with information desk and telephone switchboard, one stenographer's room, and one large library. Three general reception rooms are in connection, four consultation rooms, three treatment rooms, one large surgical room with an alcove sterilization room

Floor plan of the offices, laboratories, operating room, and accommodations of the medical service department of the Toledo Railways & Light Company, where the chief surgeon and staff for the Ohio subsidiaries of the Henry L. Doherty Company maintain a headquarters. From this department the medical service for twelve Doherty public service corporations is directed. All the offices or separate rooms are connected with extension telephones. The switchboard and information desk are located in the main hall of the suite. A system of push buttons insures quick communication between offices. The various rooms are well lighted. Sky lights are provided in the large operating room, the x-ray room, and library. The arrangement of the larger operating room and the adjoining instrument and sterilizing room, which occupies an alcove off of the operating room, makes for convenience. Besides the large general reception room, there is a reception room for men and another fitted as a rest room for women.

connected, one cystoscopic and electrical room, one laboratory, one dressing room, one rest room, and a number of supply rooms, toilets, closets, etc. One of the most convenient adjuncts is a large fire-proof vault, a feature considered essen-

tial, for the preservation of records is one of the most important functions of such a department. The arrangement is in straight lines, except in the operating and treatment rooms which have curved corners and mosaic floors. All freak ar-

ideal hospital operating-room. Each of the treatment rooms is an independent unit in which the patient can be cared for without an assistant having to run from one room to another in search of dressings, instruments, etc. Work can be carried on in any one room without interfering with the work of any other room. The plan conceived the provision for efficient emergency work that possibly must be done under great pressure, and

satisfactory. The lighting system is fairly well shown in the accompanying cuts.

The efficiency of a medical department depends largely upon complete and well arranged physical equipment; but it is even more essential to have the loyal support of assistants, associates, and nurses to carry forward a great campaign of industrial betterment. The hearty cooperation of the officials in charge was enlisted at the very

Upper portion of reverse side of report of physical examination form, which the examining surgeon prepares for each applicant for employment.

under absolutely controllable conditions. All of these objects have been accomplished very well.

There is a large air compressor in the attic as well as a large tank to contain sterile water. Each treatment room is equipped with compressed air, gas, hot and cold water, and fountain cuspidors. Each room can be readily converted for dark room work. The cystoscopic and electric room and one treatment room are finished in black. The surgery, sterilizing room, and the two treatment rooms are finished in white enamel. The surgery is constructed without woodwork. All cabinets except one instrument cabinet are built in the walls, which makes for cleanliness, space-saving, and ease of work. The doors are very large and an operating table can be readily moved from one room to another.

The remaining rooms are finished in silver gray with hardwood floors. The furniture in some of the rooms is silver gray; in others, oak. The walls and ceilings are tan. Ten windows on Adams Street give the north light which is best for most purposes. Artificial lighting is provided by the semi-indirect system and has proved very

inception of this service. The president of the company, the director of safety, and the heads of all departments have uniformly given to the medical department the fullest cooperation. All departments work hand in hand and this unity of purpose and concentration of effort undoubtedly contribute toward the full measure of service rendered by the medical department. Bulletins are used for instruction and notification and the monthly publication of a journal called "Sparks" binds together all activities and keeps the men in touch with and in sympathy for the work.

By the methods instituted in the handling of the cases for these many diversified utilities, the rate of accident claims are shown by careful figures submitted by all departments to have been reduced 38 per cent in 1918. This is proof of the accuracy of the methods used, and its great value aside from consideration of the splendid humanitarian principles involved.

Physical Examination of Workmen

A satisfactory standardization was established at the beginning of the work by subjecting all em-

ployees already in service to the same tests required of all applicants for work. The system also provides for a periodical examination of the men in service. The thorough examination of all applicants has been very valuable in days of labor shortage. It conserves the men by keeping them from unsuitable or harmful employment, and, if the physical examination demonstrates

that a man is not available for one kind of work, he may be transferred to another department and not lost entirely to the industry.

An applicant for any position with the Toledo Railways & Light Company or its affiliated companies first interviews the superintendent of employment at the company's office and if he seems a promising candidate he is given an order to

The lower portion of reverse side of report of physical examination form shown on pages 304 and 305. A surprisingly large percentage of physical defects are discovered in those who undergo examination. These reports are a valuable source from which to obtain data of almost every sort with regard to the physical deficiencies of workingmen.

report to the medical department. The first part of the examination consists of questions which include the usual queries concerning age, birth, place of residence, previous employment, etc. If these are answered satisfactorily, thorough physical examination is made by one of the assistant surgeons who notes on printed forms the conditions found. The usual blood and urine tests are made, stethoscopic examination made of the heart and lungs, blood pressure is taken, and, in the presence of evidence of any bone fracture, an x-ray examination is made and the exact condition noted. A review of this report is made by the chief surgeon who supplements it with an additional examination, noting his conclusions on special forms. The applicant must pass the color test to rule out any degree of color blindness. He is then reported back to the superintendent of employment as eligible physically. If the applicant wishes to join the railway department, he is then sent to the railway training school maintained by the company.

By carefully checking up the physical condition of new men and those already in the service, it has been found possible to maintain a much higher physical standard among the employees than had otherwise been attained. It is often found that a place in the railway department is sought by a man whose physical condition precludes his becoming a motorman, but if he is a candidate promising in other respects, he is encouraged to try for a place in some other department. Every effort is made to make the department serve the man as well as the industry.

How Injury Cases Are Handled

Except when a major operation is required, all injury cases are taken to the medical department where the necessary work is done. Only a simple dressing may be required, but equipment is available there for almost anything that could be accomplished in a first-class hospital operating room. If after such treatment an injured employee is found able to return to work, he is given an order to report back to his superintendent. If he is unable to engage in his regular duties, light work may be found for him as it has been the experience of the company that, when given something to do, men suffering from slight injuries improve more rapidly than if laid off and given full opportunity to worry about the condition.

However, when the employee returns to work he is not lost sight of by the doctor. His condition is carefully checked up by the visiting nurse who works under the supervision of the chief surgeon. She has a record each day of the men

treated by the doctor. She visits all the plants every day except Sunday, locating each man on her daily list and noting the condition of his injuries. She renews dressings when necessary and makes a daily progress report. She also supervises the condition of the emergency first-aid rooms in each plant, sees that they are in sanitary condition, and that they are supplied with the proper amount and assortment of equipment.

A glance at the list of companies shows that all kinds of utilities are included in this service. Modifications in physical requirements have been made in the routine handling of the physical examinations and methods evolved which make for the efficiency of the department; but it is not alone in raising the physical standard of the men, nor even in the periodic attention to their physical needs that the medical department is made to function.

The institution of a consistently planned system of record keeping and its enforced use in a large number of men, furnish detailed information of great value to medical science and to welfare workers. Such a system compiles data which form a basis for definite estimates of the physical needs of given groups, of the cost of supplying adequate service, and, incidentally, the value of such service, supplemented by health education, in the social welfare of an industrial group. One of the most persistent causes of failure and discouragements in efforts toward social betterment is that fact that remedial measures have been applied as extraneous measures based on insufficient data instead of being designed exactly to meet existing conditions. The medical department is able to tabulate all cases, and make deductions which afford a much more definite working basis for social betterment. In the medical field as well, such records become the most valuable guide in evolving the best methods of procedure. The second report of this service will summarize the course pursued in the several classifications of injuries.

(To be concluded)

Sensible Shoe for Feminine Wear

The kind of a shoe which American women should wear, but do not wear, has been decided upon in joint conferences of shoe manufacturers with members of the National Board of the Young Women's Christian Associations, and a publicity campaign has been instituted by the National Board among the 400,000 members of the Association, to popularize sensible shoes for feminine wear.

The Paris *Temps* announces that an organization has been formed with the object of establishing permanent relations between American and French physicians and surgeons.

MEDICAL SERVICE FOR EMPLOYEES AND FAMILIES AT THE ENDICOTT JOHNSON CORPORATION

BY L. D. FOSBURG, M.D., CHIEF OF MEDICAL DEPARTMENT, ENDICOTT JOHNSON CORPORATION, ENDICOTT, NEW YORK

THIE Endicott Johnson medical department of Endicott, N. Y., was started in January, 1917. The purpose of this undertaking was to look after accident and sick calls of employees during working hours. As the work rapidly increased, a nurse was soon added to the force. In May of the same year the work had outgrown its quarters and another doctor joined the staff. At this time the Endicott Johnson Corporation decided to extend the service and treat not only employees but their families also. In September the work increased to such an extent that still another was added to the force. In March, 1918, the office space became too small and larger quarters were secured. There are now three offices, the drug room, a laboratory, and a commodious waiting room.

The department at present consists of two branches. One is the surgical division at our tannery, where dressings are made and accidents attended. This branch is making about three to four hundred dressings weekly. Here also an x-ray room is maintained for minor cases.

Six Physicians on Staff

The medical department proper is situated convenient to the company's buildings. Here are treated all kinds of cases. The present force comprises six whole-time doctors, two office nurses, and three visiting nurses. The six physicians include four men and two women.

In taking up work of this kind there have been many difficult problems, as there have been no precedents to follow. During the six months between May 1, 1918, and November 1, 1918, the medical department in Endicott made a total of 11,442 office calls, 12,212 house calls, and 931 night calls.

It is the aim of the company in establishing this department to give employees and their families better service at no expense to themselves. The company furnishes the best of equipment. In two years time the service has been increased from one to seven doctors and five nurses, and today there are some ten thousand patients.

Do the people appreciate this service? In the main, yes. We get some very nice letters and words of commendation. They use the service freely. Many calls made result from a scratch of a pin and the like, and we encourage this because

we know it prevents infection. Many cases of constipation are treated because the people can come and get their medicine free, whereas, if they had to buy it, they would wait and appendicitis, obstruction, or other serious difficulties would follow. By having a doctor in constant attend-

This man did not neglect a sore thumb, but came to the medical department for attention.

ance infections have been cut to a very small percentage and by working with the health officers and school physician we are cutting down the infectious diseases. That is why we are treating the diseases of school children and removing tonsils. It is the policy of the company that employees shall be carefully attended by the medical department and that the school children shall be taken care of whether of the Endicott Johnson family or not. It is the custom to do all dressings, culture work, and tonsil and adenoids treatments free of charge. The school physician or school nurse has only to make out a slip and send the pupil to the office of the medical department, where they get the best of attention.

To all who are in distress or in poor circumstances the services of the medical staff are offered.

To provide for the needy in sickness and death, the Endicott Johnson Relief Department was organized. Those employees who desire may, at the small expense of ten cents per week, to which the company adds an equal amount, draw \$10.50 a week for forty-eight days each year. In extreme cases this may be extended to ninety-six days.

In Johnson City, six miles away, are located the main factories of Endicott Johnson. All tanning and fine-welt shoes are manufactured in Endicott. The Johnson City Medical Department is under construction at present. Here is located a hospital to which most of our serious cases are sent. Sickness whether medical or surgical is given free treatment at this hospital to those who are unable to pay.

We take all kinds of cases—genito-urinary, surgical, medical, or obstetrical specialties. We attend all employees and families, those in need, and any emergency we are able to meet. The corporation pays regular salaries to doctors and nurses, furnishes medicine, transportation, offices, and all necessary equipment to do the work at no expense to the employee. Free ambulance service is extended to everyone.

During last year we attended one hundred and ninety-three mothers in confinement, and this work is increasing. As far as possible we make the usual urinary examinations; the visiting nurses make regular calls before, during, and after, parturition. We feel that some day these same babies are going to make the shoes for Endicott Johnson. If we can begin training them in the right way, and help them to keep healthy, they are going to be better working men and women.

We send our tuberculous cases either to Ideal Rest, a sanatorium in which the company is interested, or advanced cases to the County Hospital for Tuberculosis.

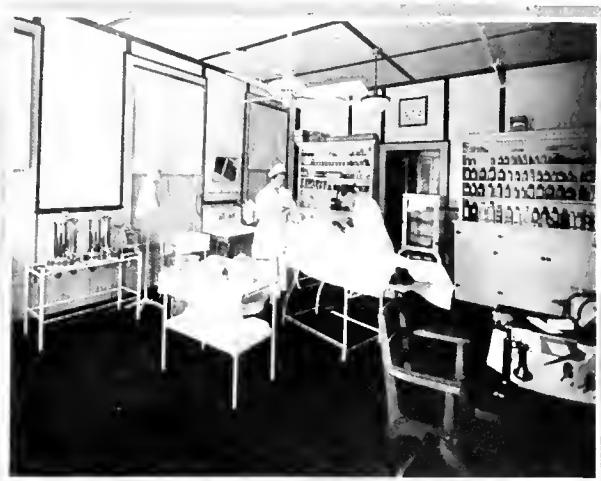

We have plans for a Contagious Hospital to care for those cases where the patient is a roomer or boarder and has no one to look after or care for him. We also have a resting place for those who are convalescing from severe illness or operation.

A plentiful stock of medical and surgical supplies is always kept on hand at the dispensaries, laboratories, and hospitals of the Endicott-Johnson medical service.

In the surgical department we have been unusually busy during the period of our entrance into the war. One surgeon has done practically all the operations. Since the close of the war one surgeon has returned and our doctor in specialties of the eye, ear, nose and throat.

The major operations included hernias, appendices, gallstones, mastoids, peritonitis, pus tubes, amputations, etc., numbering 334.

First aid at the Endicott-Johnson Factory.

Since April 15, 1919, 100 tonsil and adenoid operations have been done in the specialists department.

Contagion has been light during the past year, 177 cases being attended by us, the cases being as follows: measles, 77; whooping cough, 12; scarlet fever, 2; chicken-pox, 14; diphtheria, 8; and mumps, 64.

We have examined and sent to "Ideal Rest" 15 cases of pulmonary tuberculosis, of which number all but one have returned much improved in health and the disease has remained inactive. One case developed tuberculous peritonitis and succumbed to that disease.

The employees number about 5,000 and we have cards for about 9,000 patients from this number and their families. We average about ten new applicants daily. The latest announcement is that we are to draw up plans for a central medical department building to house our entire medical and surgical department. A maternity ward will be provided.

New Building for Medical Department

I have not, in this article, discussed minor accidents, etc., nor the major operations, of which we have several every week.

The Endicott Johnson buildings consist of five tanneries, sales building, shoe factory, fire prevention, mechanical department, carpenter shop,

paint shop, and others. The company employs workers of many nationalities. Among them are Americans, Italians, Russians, Poles, Slavs, Greeks, Lithuanians, Swedes, and others. In so mixed an assembly of workers it naturally ensues that we must have many and varied attractions. In this line it has been the policy of Mr. Johnson to provide a mutual recreation place for the people to gather. In our very midst has been

Employees report by appointment for examination or treatment by the physicians and nurses of the Endicott-Johnson medical staff.

provided a beautiful park for the employees and their families and the surrounding neighborhood. Ideal Park is situated along the Susquehanna River and is generally used by the country-side for family and society picnics.

Park Provides Wholesome Amusement

Playgrounds, merry-go-arounds, and band concerts are found, and here Sousa's Band and Marine Band appeared last year free of charge. There are provided a half-mile track for matinee races, foot races, a baseball diamond, football field, and athletic club house for boxing and club meetings, a swimming pool, dancing pavilion, stables for training horses, lunch pavilions and cook houses, and a bathhouse now under construction to accommodate at least ten thousand bathers.

In this park are about thirty carefully guarded forced wells and a pumping station, which supply Endicott and Union with pure water. The announcement was lately made that there will be a modern gymnasium added to the park, to cost \$100,000.

"Mere intellectual appreciation of the merits of a question has little value unless there is willingness to contribute time and labor to the development of the purpose involved. One is culture; the other morality."—William C. Braisted.—MODERN MEDICINE, May, 1919.

INDUSTRIAL PHYSICIANS AND SURGEONS

The tentative program of the Ninth Conference of Industrial Physicians and Surgeons, to be held in Harrisburg, Pa., September 22, 1919, has been announced as follows:

Morning Session 9:00 A. M.

Address of Welcome: Hon. Clifford B. Connelly, commissioner, Department of Labor and Industry of Pennsylvania.

"The Medical Profession and the New Workmen's Compensation Act of Pennsylvania"; Dr. Frederick L. Van Steeple, president, Pennsylvania State Medical Society, Olyphant, Pa.

"The Sanitary Disposal of Sewage and Trade Waste, and the Consideration of what Constitutes a Proper and Adequate Drinking Water Supply"; Col. Edward Martin, commissioner of health, Commonwealth of Pennsylvania.

"Recent Personal Experiences in the Present Methods in Force in Germany, England and France for the Conservation of the Worker"; Dr. Alice Hamilton, United States Bureau of Labor Statistics, Washington, D. C.

Afternoon Session 2:00 P. M.

Symposium on Health Insurance:
"State Medicine or Health Insurance—Which Would Be Best for the Medical Profession?"—for the General Public?"; Col. Benjamin S. Warren, assistant Surgeon General, United States Public Health Service, Washington, D. C.

"Have the Medical Profession Adequately Met Their Responsibilities?"—Dr. George E. Tucker, Aetna Life Insurance Co., Hartford, Conn.

"The Cost of an Adequate Medical Service Under Health Insurance"; John A. Lipp, managing editor, MODERN MEDICINE, Chicago, Ill.

DUST HAZARD IN ABRASIVE INDUSTRY

"The conviction is growing among students of industrial hygiene that the incidence of tuberculosis among the workers in dusty trades is one of the gravest problems in this field," comments C.-E. A. Winslow, professor of public health, Yale Medical School, and consultant in industrial hygiene, United States Public Health Service, in a paper on the dust in abrasive industry, which is published in *Public Health Reports*, Vol. 34, No. 22.

Professor Winslow offers a critical review of two studies on tuberculosis in industry; one conducted by the United States Bureau of Census in 1908 and 1909, and the other by F. L. Hoffman for the Prudential Life Insurance Company. He discloses a discrepancy of 25 to 50 per cent in ratios for the incidents of disease by industries, the statistics of the Prudential survey being from one-fourth to one-half higher than those for the registration area.

As both studies are parallel in the showing of tuberculosis for different classes of occupations and age periods, the two sets of figures check each other closely when allowance is made for the high ratio found in the Prudential Company's investigation.

The worst sufferers are found among the trades in which are grinders and other workers with abrasive materials. Professor Winslow notes, however, that little attention has been given to the workers engaged in the manufacture of these same abrasive materials.

The following pointed conclusion indicates the seriousness of the disease problem in dusty trades: "In general the data show quite clearly that exposure to mineral and metallic dusts, as among brass workers, marble and stone cutters, and polishers, is accompanied by tuberculosis ratios at least one-third greater than the ratio for all occupied males, and at some age periods more than twice as great."

Statistical information and comment is furnished of the investigations in three factories using abrasive materials. Trades of which studies have been made include, brick, tile, and terra cotta workers; iron and steel workers; plasterers; molders; paper hangers, painters, glaziers and varnishers; tinplate and tinware workers; jewelers, glass-blowers and other glassworkers; tool and instrument makers; potters, marble and stone cutters; brass workers; compositors and typesetters; pressmen, printers, lithographers and pressmen; polishers.

OCCUPATIONAL DISEASES UNDER WORKMEN'S COMPENSATION LAWS

BY CARL HOOKSTADT, BUREAU OF LABOR STATISTICS, UNITED STATES DEPARTMENT OF LABOR, WASHINGTON, D. C.

MOST of the workmen's compensation laws in the United States limit their benefits to "accidental" injuries—those due to an unexpected or unforeseen event, happening suddenly or violently, and producing at the time objective symptoms of an injury. Usually some variation of the word "accident," or a word of similar import, is used in the statute defining a compensable injury. Under these definitions occupational diseases, especially the slowly developing ones, are excluded from the compensation acts. A few of the states, however, use the term "injuries" or "personal injuries." Apparently it was the intention of the legislature in these states to include occupational diseases when they substituted the word "injury" for the British term "injury by accident." Several of the state compensation commissions interpreted the law in this light but, with the single exception of Massachusetts, these commissions have been overruled by the courts.

The present status as regards compensation for industrial diseases in the various countries of the world is as follows: In Great Britain and most of her colonies, especially the provinces of Canada, certain enumerated occupational diseases are compensable under the compensation acts. In most of the other foreign countries industrial diseases are not compensable under the accident insurance laws, but are taken care of through sickness and invalidity insurance systems. In the United States, however, with six noteworthy exceptions, occupational diseases are not only excluded from the operation of the various compensation acts but, because of the absence of health and invalidity insurance laws, receive no consideration whatever.

Diseases Subject to Compensation

Of the forty-four workmen's compensation jurisdictions in the United States, only six (California, Connecticut, Hawaii, Massachusetts, Wis-

Physical impairment produced by slow development of a disease that has its origin in the processes of an industrial occupation, is no less an injury than the disability caused by "accident."

This broad interpretation of the term "injury" is recognized in Great Britain and in other foreign countries. But in this country only six states and the Federal Government provide compensation for occupational diseases.

State compensation laws which do not accord full recognition to this principle need enlargement to include occupational diseases.

consin, and the Federal Government) at present provide compensation for occupational diseases. In Massachusetts and the United States this inclusion has been effected through the rulings of the commission and courts, whereas in the other jurisdictions it has been brought about by statutory enactment. The Wisconsin law is patterned after the British act and enumerates twenty specific industrial diseases which shall

be compensable under the act. These include lead poisoning, anthrax, mercury poisoning, phosphorus poisoning, arsenic poisoning, ankylosis, nystagmus, glanders, compressed air illness, several miners' diseases, and a number of diseases due to poisonous dusts, gases, and fumes. The other laws do not limit the scope but include all occupational diseases arising out of and in the course of employment. The Connecticut act includes all industrial diseases which are due to "causes peculiar to the occupation and which are not of a contagious, communicable, or mental nature." In the other thirty-eight compensation laws occupational diseases are excluded, in theory at least, from the operation of the compensation acts. This exclusion has been brought about by limiting the scope of the law to injuries by "accident," by adverse rulings of the courts and commissions, and by express provisions in the compensation laws themselves.

What Is Occupational Disease?

What constitutes an "occupational disease" under the various compensation laws? This is a question perennially confronting the courts and commissions in the United States. In those states in which industrial diseases are supposed to be excluded compensation benefits have been awarded for anthrax, dermatitis, arsenic poisoning, fume poisoning, occupational neuritis, housemaid's knee, and so on. In each case, however, the court or commission always took pains to point out that the particular injury in question was

compensable because it was not an "occupational disease." Compensation was granted not because it was a disease but because it satisfied in other respects the requirements of a compensable injury as defined by the statute or as interpreted by the court. When, then, is an occupational disease not an occupational disease?

Occupational diseases may be classified according to cause and nature of injury, as follows:

1. Diseases due to gradual absorption of poisons (lead poisoning).
2. Diseases in which the poison or germ enters the system through a break in the skin (anthrax).
3. Skin affections from acids or other irritants (eczema, dermatitis).
4. Diseases due to fumes or dusts entering the system through respiratory organs (tuberculosis, gas poisoning).
5. Diseases due to vibrations or constant use of particular members (neuritis, telegrapher's cramp, housemaid's knee).
6. Miscellaneous diseases (caisson disease, miner's nystagmus).

Non-Occupational Diseases Compensated

There are, however, two additional classes of diseases, non-occupational in character, for which compensation is usually granted: (1) Those diseases, such as typhoid fever, erysipelas, sun stroke, pneumonia, and ivy poisoning, which arise out of and are approximately caused by the employment. These diseases, to be compensable, however, must have had their origin in the employment and must be definitely traceable to it. (2) Those diseases which either result from an accident or are aggravated, accelerated, or developed by the accident. In these cases compensation is awarded not for the disease *per se* but for the results of the accident. Had the accident not occurred the disease would presumably never have developed; consequently the resulting disability is justly attributable to the accident. In this connection the Pennsylvania Workmen's Compensation Board said:

The workmen's compensation act does not prescribe any standard of health or physical condition to which the workman of the state must conform to qualify for compensation, nor does it imply a warranty on the employee's part that he is free from latent disease or physical defect which may develop into serious injury if excited into activity through his exertions in the course of his employment.¹

In theory, therefore, when an employer employs a workman he accepts him as he is and becomes liable for injuries in which the employee's pre-existing disease or defect was partly responsible.

Of the six classes of occupational diseases enumerated above compensation has been uni-

formly denied for the first class, i. e., for those diseases which have developed gradually and which are inherent in the employment. No state, except those² which compensate for all occupational diseases, has awarded compensation for lead poisoning. As regards the other classes of diseases, there has been a lack of uniformity in the practices of the courts and commissions of the several states. Numerous diverse and contradictory rulings have been made in what appear to have been identical or similar cases. For example, compensation for occupational neuritis has been awarded in one state and denied in another; a workman contracting anthrax has been granted compensation in a third state and denied compensation in a fourth; and so on.

Principles of Compensation

However, while the practices among the several state commissions and courts vary, the legal theories and principles upon which their decisions are based have been remarkably uniform. Compensation for occupational diseases has been usually granted if one or more or all of the following conditions were present: (1) if the disease resulted in violence to the physical structure of the body, i. e., if it was traumatic or produced a lesion; (2) if the injury occurred unexpectedly or not in the usual course of events; (3) if the injury can be traced to a definite time and place in the employment; and (4) if the injury was not due to a known and inherent risk of the occupation; or, even if inherent in the occupation, if the employer had neglected to provide reasonable safeguards which would presumably have prevented the injury.

The guiding principle adopted by most of the courts and commissions in occupational-disease cases is stated by the Pennsylvania Workmen's Compensation Board in awarding compensation for dermatitis due to the presence of poison in hides handled by the employee as follows:

Where injuries received in the course of employment are of intraceable inception and gradual and insidious growth and can not be traced to having been received at some certain time, and in which there is no sudden or violent change in the condition of the physical structure of the body, they must be regarded as the results of an occupational disease. However, if the disease can be traced to some certain time when there was a sudden or violent change in the condition of the physical structure of the body, as, for instance, where poisonous gases were inhaled which damage the physical structure of the body, it is an accident within the workmen's compensation act of 1915, and is compensable.³

¹Smith v. Pittsburgh Coal Co., Pennsylvania Workmen's Compensation Board decisions for 1916, p. 63.

²California, Connecticut, Hawaii, Massachusetts, Wisconsin, and the Federal Government.

³Roller v. Drueding Bros., Pennsylvania Workmen's Compensation Board decisions for 1916, p. 86.

The following list shows the various classes of occupational diseases for which compensation has been awarded in the several states. This list is by no means complete nor are the states enumerated the only ones in which the specified occupational diseases have been compensated:

ANTHRAX

Anthrax contracted through chaps or cracks on the back of the hands of a workman while handling hides (New York).

Anthrax contracted by a wool sorter through an abrasion on his neck (Pennsylvania).

ARSENIC POISONING

Acute arsenical poisoning from inhaling fumes from spelter furnace (Illinois).

GAS, FUMES, AND DUSTS

Gas poisoning resulting in cerebral hemorrhage from close proximity to gas flame (Illinois).

Breathing of poisonous gases which had accumulated by reason of insufficient ventilation (New York).

Miliary tuberculosis following inhalation of gas fumes due to an explosion (Wisconsin).

Infection of throat due to inhalation of dust from dry hides by reason of poor ventilation (Michigan).

Involuntary inhalation of gas fumes caused by explosion (Pennsylvania).

Inhalation of gas fumes from salamanders used to heat workplace (Minnesota).

Inhalation of poisonous fumes while heating bucket of paint in an insufficiently ventilated room (Ohio).

SKIN DISEASES

Dermatitis due to fortuitous presence of poison in hides handled by workman (Pennsylvania).

Abrasions and irritation of skin from acids in handling hides in tannery (Wisconsin).

VIBRATIONS OR CONSTANT USE OF PARTICULAR MEMBERS

Traumatic peripheral neuritis due to constant vibration of punch press (Illinois).

Housemaid's knee contracted by a plumber (Connecticut).

NONOCCUPATIONAL DISEASES

Typhoid fever contracted from impure drinking water furnished by employer (Wisconsin).

Erysipelas contracted from frostbitten nose (Connecticut).

Pleurisy and pulmonary tuberculosis contracted from wetting received by jumping in river in course of employment (New York).

Nephritis and disability contracted by becoming wet from flushing hot pulp from basement of paper mill (Indiana).

Ivy poisoning of railroad employee while mowing grass on right of way (New York).

It is interesting to note the paradoxical position in which the courts and compensation commissions have placed themselves. Workmen's compensation laws have been enacted in the vague belief that industrial accidents were inevitable and constituted a permanent and integral part of industrial life. The one clinching argument constantly used by proponents of compensation laws has been that a large proportion of industrial accidents were due to the inherent risk of the in-

dustry, and consequently the employers' liability system based upon negligence was no longer applicable. These same reasons, formerly advanced for accident compensation laws, are now used by the courts and commissions against compensation for occupational diseases. In accordance with their interpretation of the probable legislative intent of the statute, compensation for such diseases is denied if they are naturally inherent in or incidental to the employment and granted if their occurrence is sudden or accidental. In actual practice and as a matter of simple justice, however, commissions and courts undoubtedly feel that an employee who contracts an occupational disease is just as much entitled to compensation as one who sustains the loss of an arm. Consequently in their decisions under the law they have no doubt been influenced by their desire to remedy so far as possible the economic injustice of the statutes.

Prevalence of Occupational Diseases

The failure to include occupational diseases in the early American compensation acts was probably due, in part at least, to the lack of information as to their prevalence. It was also deemed inadvisable to burden the employer unduly. Even at present there exists no reliable statistical data showing the annual number of industrial diseases in the United States. Numerous investigations of the occupational-disease hazards of particular industries have been made, a number of which have been published by the United States Bureau of Labor Statistics. The morbidity rates for lead poisoning in certain trades and industries have been especially high. Some idea of the prevalence of occupational diseases, however, may be obtained from the Massachusetts statistics. For the two years ending June 30, 1917, there were reported to the Massachusetts Industrial Accident Board 2,385 occupational diseases which resulted in loss of time; 42 of these were fatal. The 1,351 nonfatal diseases reported during the year 1915-16 resulted in 31,333 days lost time, or an average of 23 days per case.

Massachusetts also has a law requiring certain specified occupational diseases to be reported to the State board of labor and industries. Under this law there were reported to the Massachusetts board during the three-year period 1915-1917 the following occupational diseases (Table I):

Occupational Diseases in Foreign Countries

Occupational diseases have been compensable under the workmen's compensation act of Great Britain since 1906. The law as amended that year provided that certain occupational dis-

eases enumerated in the act should be compensable if they were due to the nature of any employment in which the workman was employed at any time within one year previous to the date of disability or suspension. Compensation shall be recoverable in the first instance from the last employer. The latter, however, may recover from other employers whose employment had within the year contributed to the contraction of the disease. The compensable occupational diseases specified in the act are anthrax, lead poisoning, mercury poisoning, phosphorus poisoning, arsenic poisoning, and ankylostomiasis (miner's hookworm).

The Secretary of State for the Home Office was authorized to extend the provisions of the act to other diseases and processes. In accordance with this authority the scope of the act as regards occupational diseases has since then been considerably increased. In 1907 (order of May 22) sixteen new diseases were added to the original list. These included nystagmus, glanders, compressed-air illness, several miner's diseases, and a number of diseases caused by poisonous fumes and acids. The original scope relative to lead and mercury poisoning was also enlarged. Cataract in glassworkers and telegrapher's cramp were added in 1908 (order of December 2); writer's cramp in 1913 (order of July 30); dope poisoning in aircraft production in 1915 (order of July 7); and poisoning by dinitrophenol and tetrachlorethane in 1918 (order of February 28).

Compensation for dermatitis, ulceration of the skin, and ulceration of the mucous membrane of the nose and mouth, produced by dusts and liquids, is not allowed if the employee is disabled only for employment in the process in which the disease was contracted. Compensation for cataract in glassworkers is limited to not more than six months, and to not more than four months unless an operation is had. Compensation for writer's cramp is limited to a period of twelve months.

The number of occupational disease cases contracted and compensated in 1914 under the British workmen's compensation act is shown in Table No. II.

Of the total of 6,061 cases of occupational disease shown in Table No. II, 5,547, or over 91 per cent, occurred in the mining industries.

The importance of occupational diseases as compared with industrial accidents may be seen from the following facts: The total number of industrial accidents in Great Britain in 1914 was 400,622, of which 4,216 were fatal and 396,406 were nonfatal. The total amount of compensation paid out in 1914 on account of industrial accidents was £3,275,711 (\$15,941,247), of which

TABLE NO. I
NUMBER OF OCCUPATIONAL DISEASES REPORTED UNDER MASSACHUSETTS COMPENSATION LAW IN THREE-YEAR PERIOD OF 1915-17.

Occupational disease	Total number reported	Fatal cases reported
Anthrax	82	13
Benzol poisoning	8	5
Brass poisoning	18	..
Caisson disease	31	1
Cigar neurosis	3	..
Amyl acetate	2	..
Dermatitis	14	..
Fume and gas poisoning	49	13
Lead poisoning	296	2
Miscellaneous	9	1
Total	512	35

TABLE NO. II
NUMBER OF OCCUPATIONAL DISEASE CASES CONTRACTED AND COMPENSATED IN 1914 UNDER WORKMEN'S COMPENSATION ACT OF GREAT BRITAIN¹

Occupational disease	Number compensated
Anthrax	36
Lead poisoning	344
Mercury poisoning	6
Phosphorus poisoning
Arsenic poisoning
Ankylostomiasis	4
Benzine derivatives poisoning	19

Nitrous fume poisoning	3
Nickel carbonyl poisoning
African boxwood poisoning
Chrome ulceration	28
Eczematous ulceration of skin	46
Epitheliomatous cancer	19
Serotal epithelioma
Nystagmus	2,775
Glanders
Compressed air illness	1
Miner's beat hand	817
Miner's beat knee	1,609
Miner's beat elbow	165
Inflammation of wrist joint of miners	181
Cataract in glassworkers	4
Telegrapher's cramp
Writer's cramp	1
Total	6,061

£672,633 (\$3,273,368) was paid out for fatal cases and £2,603,078 (\$12,667,879) for nonfatal cases. The total amount paid out on account of occupational diseases during the same period was £189,650 (\$922,931), of which £7,099 (\$34,547) was paid out for fatal cases and £182,551 (\$888,384) for nonfatal cases. The amount paid out on account of occupational diseases during 1914 was therefore 5.8 per cent of the amount paid out for industrial accidents; whereas the total number of

¹Statistics of compensation under the workmen's compensation act during the year 1914.

occupational diseases contracted during 1914 was 1.5 per cent of the total number of industrial accidents sustained during the same period.

In their treatment of occupational diseases the Canadian provinces have followed in the footsteps of Great Britain. Nova Scotia, Manitoba, and British Columbia adopted verbatim the occupational disease schedule in the British act of 1906. Ontario and Alberta added miner's phthisis to the original list. New Brunswick also copied the British law but did not adopt the schedule. Instead the New Brunswick act confers discretionary power upon the workmen's compensation board to declare what occupational diseases and processes shall be covered by the compensation law. Quebec and Saskatchewan are the only provinces of the Dominion which have thus far failed to provide compensation for industrial diseases.

Of the other foreign countries a few, including Argentina, Brazil, New South Wales, Switzerland, and the Union of South Africa, specifically award compensation for occupational diseases; but in a majority of these countries such diseases are excluded from the operation of the accident insurance law. This does not mean, however, that industrial diseases are not compensated. In most of the European countries they are taken care of through compulsory sickness and invalidity insurance systems although there seems to be a tendency in some of these countries to put occupational diseases under the accident insurance laws.

INDUSTRIAL CASUALTIES IN PENNSYLVANIA REACH HUGE FIGURE

A report of three years' administration of the Workmen's Compensation Act of Pennsylvania, submitted by Lee S. Solomon, secretary, contains the following statement:

"A grand total of 668,340 accidents in this state in three years shows, at a glance, that the losses in industry in Pennsylvania make fair comparison with the casualty lists of a military army in field service. While it is true that a great portion of the accidents reported were of a minor nature, and did not even fall beyond the two weeks waiting period of the compensation law, because of the effective medical service provided by the Act, yet little or no progress has been made towards the prevention of fatalities."

The deaths occurring in 1916, 1917, and 1918, numbered 9,143, reflecting to some degree the tension under which industry operated during the war.

The sum expended for relief of victims includes an item of \$3,138,014 which was paid in fatal cases, and the burden of cost shows the following expenditures: exempted companies, \$2,002,239; insurance companies, \$869,791; State Workmen's Insurance Fund, \$265,983. There was \$9,158,833 expended in the relief of disability cases in three years, this cost being carried as follows: exempted companies, \$4,322,944; insurance companies, \$4,436,108; State Workmen's Insurance Fund, \$399,780.

HEALTH WORK FOR WHITLEY COUNCILS

About a year ago the Whitley Councils of the Potteries and Printers set up a joint health committee which sanctioned an experimental scheme for regular medical observation and research in industry. The experiment, described by Mr. E. Halford Ross in a lecture delivered on Tuesday last before the Industrial Reconstruction Council, was made in two large printing works, where the employees were informed by both their employer and the secretary of the trade-unions that a doctor would attend periodically to advise the workers on health matters. As a result many came forward and asked advice. Observations were made while work was in progress and much was done to show employees how they might work under better conditions. In addition, numerous cases of disability were discovered and remedied and the experiment was considered to have been most successful. Certain researches were done concerning fatigue, hours of work, the provision of seats, and the advantages of welfare work generally. It was discovered that the health committee of each industry is the best means of carrying out this work. Each industry differs; each has its own requirements. It is, therefore, much better for each industry to undertake its own welfare matters than to leave it entirely to any Government department. This experiment suggests that further valuable research in industrial medicine might be carried out on a larger scale under similar conditions. Sufficient work has already been done in London during the last two and a half years to indicate some of the lines along which research should be pursued. Catarrh, bronchitis, and chronic cough are the most common obvious ailments which affect the workers, and it is very rare to find a large office without somebody in it suffering from a "cold." It is quite certain that a considerable sum of money is lost in London every week owing to the reduction of output caused by these complaints, in addition to the wages paid during sickness. It might quite possibly be demonstrable by experiment that economy would be effected if workers suffering in the early stages of catarrh were persuaded to stay at home until they recovered. Anaemia is also of frequent occurrence among the young women and girl workers, and handicaps their work greatly. Out of several hundred employees examined in three large clothing factories 63 per cent of the girls were found suffering from anaemia. This common disease can be easily prevented if taken at once when it appears. If left until well advanced each case may require months of treatment. Its prevention is a matter of education, and a little medical advice to parents in childhood will stop much of this disabling affection. Here is a matter which an industrial medical service could take up at once, and in which, working in conjunction with the School of Medical Service, it would achieve wonders in a very short space of time. Anaemia has a most distracting effect on work, and may last for years, producing far-reaching results in motherhood. Again, from work that has been carried out in connection with munition works during the war it appears probable that improper feeding has been a considerable factor in the production of fatigue, and that the short, hurried, and scrambled midday meal, accompanied by the discomfort of waiting in queues and the curtailment of rest, has resulted in a diminution of output. These questions are for scientific study rather than for political speculation, and under the aegis of the Whitley Councils medical men might well find an opportunity for impartial observation in a sympathetic environment.

AN INDUSTRIAL UTOPIA

DIVIDENDS FROM HEALTH-BUILDING

Attention to the well-being of employees in working hours and care of employees or members of their families during sickness promotes stability in the organization of Montgomery Ward & Company and in the homes of their workers. The medical service is a producing department. Some of the products are:

- Healthier girls and happy mothers.*
- Less sickness and better workmen.*
- Home hygiene and contented workers.*
- Good housekeeping and thrifty wives.*
- Regular habits and steadier work.*
- Less time-off and better morale.*

SEVEN YEARS OF INDUSTRIAL MEDICAL SERVICE FOR MONTGOMERY WARD EMPLOYEES

By JEANNETTE D. KING, MEDICAL DEPARTMENT, MONTGOMERY WARD & COMPANY, CHICAGO, ILL.

Does it look like a modern Utopia? It is "Warrenville," the haven of health where girls are sent for a rest when signs of fatigue.

IN talking with a friend the other day about labor conditions, their causes and their cure, I told him I thought the solution lay in a greater solidarity between employer and employee; an understanding, on the part of each of the other's needs. When I had finished my rather impassioned cure-all he said: "Yes, your solution would solve, all right, but it will never be done this side of Utopia." As I was only describing the working out of the problem at our plant, I am taking for my paper the title which his comment suggested.

For the past fifteen years Montgomery Ward & Company have had a doctor and a nurse in their plant, but it is only within the last seven years that the medical department has been organized and operated with as much system as any other department in the organization.

A Plan of Sickness Insurance

On July 1, 1912, there was a revolution. The old doctor who had listened to the pitiful tales of the employees and their families, and the nurse who gave them an occasional headache tablet when she was not too busy making herself a new gown, were obliged to step aside to make room for an up-to-date and efficient medical director and his force of wide-awake doctors and nurses. At that time, every employee automatically became a member of our Insurance Group which is still in effect and which is maintained by the com-

pany. This entitles every employee to free medical care in his home and in the hospital; in addition to this, the death benefit in connection with this insurance entitles the widow of one of our men to 25 per cent of his salary, to be paid weekly until she re-marries, and 20 per cent to each child until he is sixteen years of age. The beneficiary of an unmarried person receives one year's salary, to be paid at once, and in addition, \$100 for the burial.

Resident Physician at Plant

Dr. Frank Wieland, the medical director, does all of our surgery and is called in counsel by the other doctors. We have a resident physician who devotes the entire day to the work at the plant, an examining physician who spends several hours each day at the plant, and a physician who looks after the outside work.

Each department sends the names of all employees who are at home on account of illness, to the medical department, before nine o'clock each day. If such employee wishes the doctor to call, a doctor is sent the same day; if he does not, but fails to return to work on the second day, the visiting nurse makes the call. The visiting nurse also follows up all doctors' calls and gives bedside care when necessary.

All of our hospital cases are sent to the Hahnemann Hospital, and we find that they receive much better care than if we sent them to different

hospitals; the internes and nurses seem to take a personal interest in Montgomery Ward employees.

A most kindly feeling exists between the medical department and all of our employees, especially the foreign and the poorer classes. We make them feel that it is not a charity, but that they are entitled to our services.

Same Service to All

There is no royal road to health here. If Mike, down on the packing floor, requires an appendectomy, or any of our executives wishes to have an operation of any kind, they go to the same hospital, are operated upon by the same surgeon, have the same nurses, the same gas pains, and the only difference is that Mr. Executive usually returns to his home a day or two sooner than Mike, because Mike likes hospital care and the nurse's attention so much that he begs to remain until the end of his second week. In addition to furnishing the hospital care, we also pay for any special treatments which our medical director deems necessary, such as special nurses, massage, baths, osteopathy, vaccines, etc. We furnish artificial limbs and eyes, special shoes for deformed feet, crutches, etc., to our insurance members.

When a person seeks a position, he is given a physical examination; if he does not pass the examination, he is not employed, unless he has some defect that can be corrected. Decayed teeth must be taken care of as soon as possible. At the end of a year, he automatically becomes a member of our Insurance Group.

During the past two years, we have employed two girls who are stone blind; they are splendid typists and dictaphone operators, and do excellent work. We also have several cripples, many cardiac cases, and a good many deaf and dumb employees. Since we promise to pay all hospital and sanitorium bills, we must be very watchful of our people and not allow incipient cases of tuberculosis to become second- and third-stage cases before we do anything. How shall we find incipient cases is the question that comes to our mind. There are no chest findings, perhaps,—no cough, no night sweats,—but still the afflicted ones are below par. Then again, how will you compel a faithful employee who has worked for you for years, to come to you for examination? They won't do it; they think complaint has been made

about them, and they would rather leave than be subjected to an examination. We feel that we have solved the problem. In our institution we have a woman's club, composed of women from every department. Each member of this Club, as well as division managers, make it their business at all times to be on the alert for any person who is lagging in his work, or who is below par. The names are sent to us,—we look them over, and offer to put them on the malted milk list.

We serve an eight-ounce glass of malted milk between 9:30 and 10:30 o'clock in the morning and 2:00 and 3:00 o'clock in the afternoon; for we have found that at these times workers begin to lag, and this is a real refreshment which tides them over until meal-time. The vital nutritive elements of clean milk and select malted grain as supplied by Montgomery Ward & Company constitute a complete food with positive health giving qualities. Strength and energy are stored in every glass and it is so easily assimilated that it readily yields the maximum of stamina-creating power when used between meals. I find that many of our people, having been so greatly benefitted, have carried the good news home, and the entire family have acquired the habit. Should a person be unfortunate enough to be obliged to eat food which has been prepared by a cook ignorant of food values,—or poorly cooked food, we have

Summer at Warrenville. The large veranda extending around two sides of the house is used in summer as a sleeping porch by the girls from city homes who come here to rest and to repair their vitality.

the satisfaction of knowing that she will not die of starvation while in our employ. Each person on our malted milk list is weighed each month; if we find anyone losing weight, or not gaining, it is quite easy to persuade him to submit to an examination. If there are no chest findings, then we take an afternoon temperature and perhaps an x-ray. If there is no evidence of tuberculosis, then we send the girls to our country home at

Warrenville, Ill., which we own and operate. This home is located about twenty-five miles west of Chicago, and here we are prepared to take care of twenty girls at one time; these girls are not sick, but just tired, and need a rest.

It is amazing to learn how few people know what to do with a vacation. A great many look forward to spending their two weeks in cleaning house, or taking care of their sister's children while sister goes to the country; very few know that they should have an entire change of scene and a relaxation. By having this wonderful home, which is absolutely free to our employees, we have no trouble in persuading our girls to go to it. I sent a little Polish girl of eighteen out to Warrenville recently, who is the eldest of nine children. She had not been out of the city in all her life. While we were waiting for the train, I said to her, "Now I don't

want you to think that Warrenville is a big place with many attractions, for it is not; we haven't even a movie." She replied, "I haven't been to a movie for eight weeks; you see my friend takes me to the picture-show once a week, but he has been sick for eight weeks, and mother couldn't afford to let me go and pay my own way."

Now, I really admire mother for feeding and clothing nine children, in these days, with only three wage-earners in the family,—but I do feel sorry for little Antoinette too. Imagine the size of those eyes of hers when she is urged to take a second helping of chicken and all the real butter and milk she wants, and a large cut of cocoanut pie!

Rest Benefits Permanent

We have very few rules at Warrenville,—just as few as seem necessary to satisfactorily govern our community life there.

The house is quiet between one and three in the afternoon, when the girls undress and go to bed. Then they retire at 9:30 o'clock. They sleep on the porch, where we have canvas curtains in case of rain. We have listened patiently to such a variety of reasons why they cannot sleep in the night air when they are at home; but we have yet to hear the first complaint from anyone who has been at Warrenville. We have a tennis court and croquet, and a recreation room where they may dance. Last year was our first at Warrenville, and we found that the girls gained from five to

twenty-seven pounds in from two to eight weeks. In most cases, they retained their weight, so that those who went last year do not need to go this year. Not one of the thirty-three who were there had the influenza and none of them lost any time from work all winter and spring. Most of the girls had so much more "pep" that they were given better positions and were able to keep them. Does Warrenville pay? It certainly does. We

The dispensary at the Chicago plant of Montgomery Ward & Company.

have added to our quarters this year so that we are able to take care of twenty at a time instead of only ten.

In regard to our plant dispensary—we have a large waiting room, which is used by both dental and medical departments. In order to save time, no employee is admitted to the doctor, unless an appointment has been made, except in an emergency. We feel that every minute counts, and if we keep a man half-an-hour today, his supervisor will not be so willing to let him come tomorrow. We have a men's dispensary, a women's dispensary, two examining rooms, and two private offices. Then, we also have a girls' rest room, under the supervision of a nurse who takes care of minor ailments. In this room, we have comfortable cots, where anyone may lie down until she feels able to return to work. The nurse offers hot water bottles, makes a note of the time of the arrival of each, and if anyone spends too much time in bed, we investigate and relieve distress in any way possible. The nurse also keeps a supply of shoes, stockings and skirts for the use of the girls who may have been caught in the rain coming to work. The clothing is dried and made ready for the employee to wear home at night. A stock of umbrellas is also kept, to be loaned to anyone who neglected to bring one from home.

In our work we find much need for dentistry. Three years ago we installed a dental department. At present, we have six dentists giving part time.

They are all men who have been graduated from two to five years and who have their own practices. All dental work is done except orthodontia and x-ray; it is done at cost, and where an employee is able to pay for such work a certain amount is taken out of his pay each week. If he is not able to pay, then we take care of it through our welfare department. There is, therefore, no excuse for neglect of teeth on the part of anyone. Our dentists cooperate with our doctors, and we are able to do so much more good than if we had to depend on dental clinics where the quality of work is not known. Seventy-five per cent of our sicknesses are the result of infections in the teeth, and it is both convenient and satisfactory to have our own dentists, who examine the patients and report at once if there are any devitalized teeth where there is a possibility of infection. No time is lost in taking an x-ray, and we have the teeth taken care of at once instead of trying all sorts of rheumatism medicine and vaccines to effect a cure. We are working for the interest of the employer as well as for the employee, and it is to the interest of the former that a patient be made well just as quickly as possible. We feel that our dental department is invaluable; it is

is an employee or a member of an employee's family. She is often asked by young husbands to assist in bringing order out of chaos which the arrival of a new baby generally causes; she plans with the new housekeeper how to live within her income and directs the young mother regarding the baby; she is often able to persuade expectant mothers to keep away from midwives, and arranges for her care at the hospital without ex-

A library is operated in connection with the Educational Department, as a branch of the Chicago Public Library.

pense, when necessary,—and we feel that we have really accomplished something when the mother returns from the hospital with the new baby in her arms, singing the praises of up-to-date methods; we know that she is a harbinger of good in her community, and will help to teach her

poorer foreign friends and neighbors.

From our staff of welfare workers, there is always a responsible woman available to accompany any girl who has become involved in any difficulty, to a court-room; while she may not be able to accomplish anything personally, the moral support her presence gives to the girl is always most noticeable and well worth the effect, as fuller consideration of her case is generally given.

In our welfare department, there is a large, airy room, where the girls are permitted to dance, sing and enjoy recreation of various kinds during the noon-hour. On Fridays, in this room, we provide entertainment for all,—sometimes it is a lecture, sometimes a musicale, and often a lecture with stereopticon views.

In connection with the educational division, we

operated at very little expense to the firm and at very reasonable rates to the employees.

Although our welfare department is entirely separate from the medical department, we keep in close touch with each other. We employ a nurse who visits the families of the employees, makes calls in case of death, whether the deceased

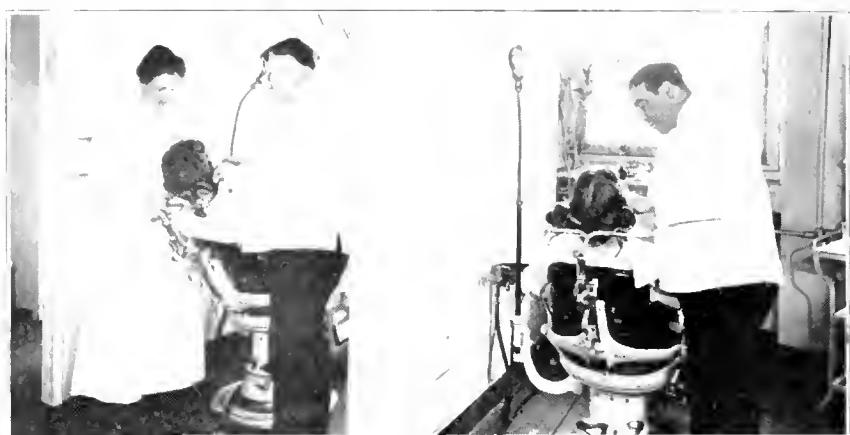

have a library, which is a branch of the Chicago Library. The city furnishes the books free; the company furnishes the room and a competent librarian who carefully selects the books for our shelves. A supply of approved technical books on business subjects, advertising, office management, scientific business management, etc., is always available, and our employees are encouraged to avail themselves of these opportunities for acquiring valuable knowledge. Similar libraries are maintained in our branch houses. At Chicago the circulation is about 5,000 books a month.

Another feature of our welfare work was the founding of the LaSalle Unit, an office force consisting entirely of colored women. September, 1918, marked the beginning of a unique experiment which opens to colored women an entirely new field of endeavor. Conceived under the stress of war-time labor conditions the Unit has now passed the experimental stage and bids fair to become permanent. The work done is part of the work of the Entry division and is entirely clerical in nature. The office force must be proficient in the operation of bookkeeping machines. Super-

vision lies with colored supervisors, two of whom are college women. The head supervisor is directly responsible to the manager of the Entry division for the proper performance of the work in this Unit. Practically none of the girls employed had any previous experience with office work or any knowledge of typewriters or other office machines. It was absolutely necessary to start it from the beginning. Progress has been

such as to prove the adaptability of colored girls for this kind of work and warrants the belief that the colored girl of the future, given training, will become as efficient as the colored girl of the past has been as a cook or housemaid.

The Unit has a large light office of its own. The girls enjoy practically the same advantages as the white girl. Wages are scaled so that after

A dental clinic under charge of experienced dentists is one of the indispensable features of the service.

a period of instruction each operator is paid according to her output. Thus each operator's wage depends entirely upon herself. They work eight hours a day (noon on Saturdays) with four ten-minute rest periods and forty minutes for lunch each day. Their meals are brought to them from the House refectionary and served at cost.

Free medical attention is given them. For recreation they have their own piano which during rest periods and lunch hour is never quiet. On the day of the House picnic the girls of the Unit had their own picnic which still furnishes a topic for conversation. That the girls appreciate this opportunity to engage in a class of work hitherto denied them and that they value the advantages and privileges which they enjoy is attested by the fact that when the call goes out for new help there are always more eager applicants than there are postions to be filled.

It is generally conceded that the plan as worked out in the past seven years so transcends in importance any consideration of cost that our schemes grow more ambitious every day. It will be quickly recognized that a large sum of money has been expended yearly by Montgomery Ward & Company for preventive and corrective meas-

Practically none of the girls employed had any previous experience with office work or any knowledge of typewriters or other office machines. It was absolutely necessary to start it from the beginning. Progress has been

ures, but our management thinks in terms of big ideas as well as big sums of money.

A "mere Utopian dream" do you still think? It will be most interesting to watch developments in the next seven years. Was it not Disraeli who said, "The impossible will be accomplished tomorrow?" Scientists "proved" the impossibility of flying,—but the Wright brothers flew, and so to me Utopia for our plant does not seem far distant.

SIMPLE HEALTH LITERATURE FOR EMPLOYEES

BY EDWIN A. HUNGER, ROCHESTER, N. Y.

[*How the Eastman Kodak Company drives home to its work-people ordinary health rules by means of health booklets and monthly bulletins.*]

Keep everlastingly at it, is one of the abiding maxims of Dr. G. L. Howe, physician in charge of the medical department of the Eastman Kodak Company, in his efforts to make the employees understand ordinary health rules and persuade them to take proper care of themselves. One of his most potent means of influencing the work-people is a simple little health bulletin which is published each month.

In this little publication—it seldom goes beyond 500 words—Dr. Howe takes some pertinent and timely health topic and in the simplest language possible tries to drive home precepts and advice that will help the employee keep his body in good order and therefore be steadier and more efficient in his work.

In the winter months grip and colds are prevalent and a topic relating to these may be chosen; similarly in summer such important subjects as "How to Keep Well in Summer," and "Typhoid Fever," have been dwelt upon in the bulletin. Then again, there are topics that are always of interest to workmen, such as the following, which have already been covered in the bulletin: "A Few Facts About Foods," "Some Popular Errors," "Importance of Attention to Small Injuries," "Mouth Hygiene," "Remedies for the Home," "Rest and Sleep," "Rupture," "Burns," etc. Records are kept of all illness among employees and quite frequently the prevalence of some ailment or disease at a certain time will also suggest a topic for the bulletin. For instance, recently it has been found that a number of men have been having boils; hence, in the near future the bulletin will appear with some useful information on the prevention and easy eradication of boils.

News Element in Health Booklet

However, the articles in the bulletin are "tied in" with some topic which at the time is very much in the minds of the people. In one of these articles recently published, for example, entitled, "Preparedness in the Body," the body is compared with one's country, the germs which cause blood poison being the enemy, the skin the first-line defense and the white blood cells the second line. In this article the readers are told that if the body is weak and unprepared and cannot resist the onslaught of the enemy, the germs, there is nothing but defeat which of course means death. The message with its parallel then so prominently in everybody's thoughts, undoubtedly went straight home with every employee who read it.

The bulletin is printed on a single sheet seven by six and a quarter inches and is folded once so that it has four pages of reading matter including the frontispiece. Eleven

thousand copies are printed each month and, owing to the simplicity of make-up, the cost is small (\$45 per issue) compared to the great amount of good that it does.

A profusely illustrated booklet entitled "Good Health and How to Keep It" has also been prepared by Doctor Howe and is freely distributed among the employees of the Eastman Kodak Company, a special point being made to hand one to each new employee immediately after the physical examination which he must undergo. This booklet is also printed in simple language so that any workman can understand it.

Photos Visualize Health Maxims

The illustrations are so chosen that the various health ideas can be easily visualized. For instance, to impress upon the mind of the reader that it is important to drink plenty of water every day one of the illustrations shows six glasses of water and underneath it is printed, "The Amount of Water You Should Drink Every Day." Another shows a toothbrush with the caption: "One of the Best Investments You Can Make for Twenty-five Cents." "Simple Foods Are Nourishing," "Types of Indigestible Foods," "Foods of Value in the Prevention of Constipation," "Frying the Worst Way to Cook Food," are titles of other illustrations.

Advantage is also taken of contrasting illustrations to put over a health lesson. Two of these side by side, one showing a set of bad teeth and the other one of good teeth with "What Can You Expect From Such Teeth as These?" and "These Teeth Can Chew Food Properly," printed underneath them tell a story with a message that makes one "sit up and take notice" as persons slantly inclined might want to say. The improper and proper way to walk are the subjects for other contrasting illustrations. Both front and back covers are attractively illustrated with outdoor sports subjects and at once give a pleasing tone to the booklet.

Health Booklet Replaces Almanac

The booklet is divided into eight short chapters with the following titles printed as rules: Rule 1—Eat the Proper Amount of Good, Nourishing Food; Rule 2—Breathe All the Fresh Air You Can at All Times; Rule 3—Get Some Form of Exercise Every Day; Rule 4—Get Sufficient Sleep Under the Proper Conditions; Rule 5—Keep the Body Clean at All Times; Rule 6—Be as Regular as Possible in All Your Habits; Rule 7—Be Temperate in All Things; Rule 8—Wear the Proper Clothing.

The booklet contains twenty-eight pages five by seven inches in size. It has proved very popular, so much so in fact that many of the workmen take them home and hang them up in convenient places by string just as people used to do with their almanacs so that they can always be readily referred to. Thus far, close to 25,000 copies have been printed and the demand for them seems to never let down.

"The same fight against preventable diseases that is made in cities should be made in the rural districts."—Governor Burnquist of Minnesota, Message to Minnesota Legislature.

Properly fitting shoes of correct shape with a straight inner edge are the most effective preventive of weakfoot, bunions, corns, callouses and painful joints, according to the United States Public Health Service. Except for paralysis, clubfoot and deformities resulting from injuries, most foot trouble is caused by improper shoes.

EMPLOYEES' HOSPITAL OF FAIRBANKS, MORSE & COMPANY

BY C. F. N. SCHRAM, M.D., SUPERINTENDENT, HOSPITAL
DEPARTMENT, BELOIT, WIS.*

OUR MOTTO FOR THE YEAR 1919

"Good, better, best,
"We shall not rest,
"Until our good is better,
"And our better, best."

Each year is proving more and more the value of the industrial physician and the industrial hospital. This realization by the executives of Fairbanks, Morse & Company finds expression in the construction of a new hospital at Beloit, Wis., providing about three times the space of the present Fairbanks-Morse Hospital. The new building will be opened this season.

The physician is no longer the "Company Doc" in the Fairbanks-Morse organization, even though that be his usual appellation; and the hospital is not the "first aid" room. It is not meant that the old time species of "Company Doc" is extinct, but hibernation has no place in the busy plant. The progressive industry to-day is demanding the same efficiency in its hospital department that it does in its production department.

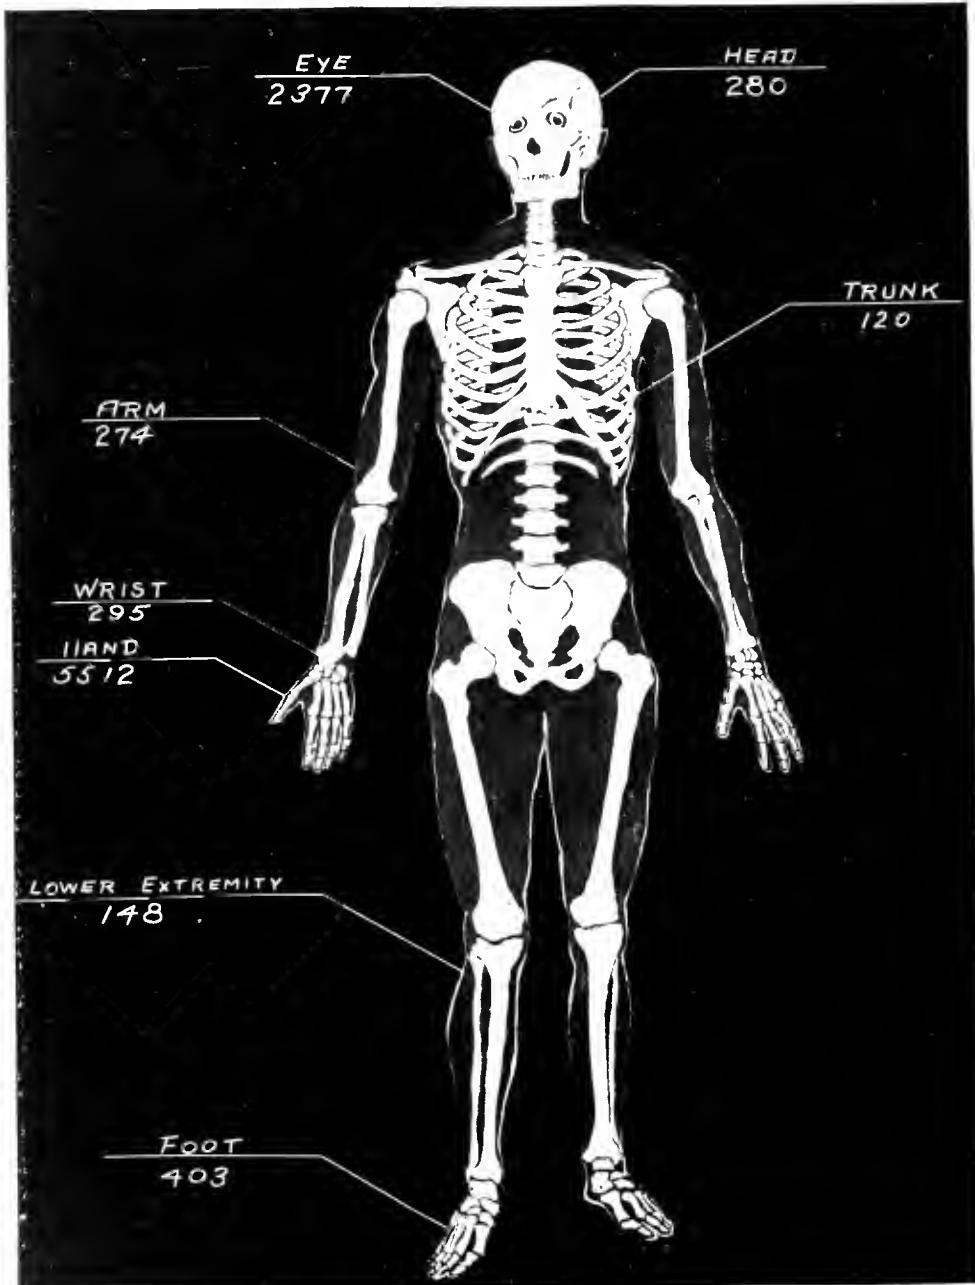

The Fairbanks-Morse Hospital serves 3,500 employees. To provide adequate hospital care for this number of employees requires a progressive hospital department. The Fairbanks-Morse Hospital looks forward to a widened field, while in the past it presents a record of service which speaks for itself.

The report of the Hospital Department for 1918 is graphically pictured in diagrams reproduced here. However, these do not make a complete report of the hospital, *i.e.*, the redressings and after-treatment of each injury is fully as important as the first treatment, and yet we can get it down in totals only (37,000) in round numbers—four times as many as the new cases. Much credit is due the nurses and recorder—in their pleasant

meetings with the injured day after day, and no injury gets well soon enough to suit the injured.

During the year 1918, a staff of one, full-time physician, two nurses and a recorder, took care of 9,409 injured employees. The redressings on these patients numbered 37,742. "Busy" was the word to use in describing the Shop Hospital at this plant for last year and yet men never had to wait for dressings.

We have no waiting room for our hospital and therefore the patient gets treated immediately upon his arrival. There are no appointments for redressings; the men coming in when most convenient for them. The hospital is

Injuries are here shown according to regional occurrence. These involved 9,409 accidents (1 fatalities), 37,742 dressings, and 4,084 cases of illness.

for the workers only and does not take care of cases of illnesses. Employees suffering from headache, constipation, sore throat, or catching colds, are given cor-

rective advice and prophylactic treatment. Four thousand and eighty-four such treatments were given last year. Whenever an employee feels that he must go home on account of sickness or if he has a temperature of 101 Fahrenheit he is sent home and advised to call his family physician.

Visiting Nursing Service for Employees

For the year 1918, 3,938 calls were made by the visiting nurse and physician. A visiting nurse driving an automobile makes calls on any case of illness of any employee or of any member of his family.

The sanitation of the shop under Mr. Lhotak, has received good care and he has ever been ready to cooperate in any way to keep the toilets' floors, telephones, and drinking fountains in a clean and sanitary condition.

In explanation of the diagrams, it may appear that they should show a large total of work done by the hospital; yet, we feel that our percentage of accidents is low when the hazardous work that our men are doing is taken into consideration—0.08 per cent—this being the daily average, or less than one to every one hundred shop employees. In considering only the lost-time accidents, there was less than one per four thousand shop employees.

The estimated expense per visit at the hospital was about thirteen cents, for 55,193 treatments and calls.

The assistance rendered our employees and their families during the smallpox epidemic of the Spring of 1918 and the influenza epidemic of the following Autumn, certainly deserve mention. Twenty-five hundred of our employees and members of their families were vaccinated in the Shop Hospital at that time. This, with the redressings of the sore arms, was in itself "some task," and yet there was no delay or postponement of our regular work.

The influenza epidemic, when at its height, in taking away daily from work over 600 men, gave us some anxious moments and work. The company's hospital in the Adams' house is covered in a separate report. It is only necessary to add here that the report illustrated Beloit's need of a City Hospital.

Quite a number of our women employees have learned

the rudiments of nursing at the Shop hospital and have assisted in the homes of many of our sick.

Schematic classification of nature and location of injuries to the foot, 403 cases during 1918.

The number of accidents from January 1, 1918, to January 1, 1919, totaled 9,409. The nature of these injuries appear diagrammatically as shown.

A total of 5,512 accidents to the hand occurred in 1918. Locations are as shown on chart.

The Hospital Department is technically the head of the Welfare Department. However, we do not feature any welfare work and yet there is the best spirit of cooperation and helpfulness throughout the Beloit plant, and good deeds and big ideas followed by big acts abound. In fact, the hospital staff resent the word welfare when applied to their department, for they contend that they are as busy building engines, windmills, and pumps, as any department in the plant. Hospital production being "injured men at work," therefore no time can be wasted in waiting for dressings.

Staff Physician Inspects Plant

The staff physician is out through the plant quite a bit of the time checking up on suggestions as to drafts, gas fumes, and general hygienic measures. The entire shop was posted in reference to influenza before a single case was reported in Beloit.

A new hospital is planned and will be opened this season providing about three times the present space with a modern Roentgen-ray outfit, laboratories, and a six-bed ward. Rooms for examination of new employees will be provided also and all employees going home sick will report at the Shop hospital and again upon returning to work. The idea we are working on in Beloit is not to reject the physically handicapped but to fit the man to the job and with more spacious quarters, we shall be able to carry out this program much better.

THE JOURNAL OF INDUSTRIAL HYGIENE

Caustic criticism of the industrial physician or surgeon who makes a hit-and-miss diagnosis of accident cases which he does not take the trouble to fully understand, appears in the July number of the *Journal of Industrial Hygiene*, in an article from the pen of Robert B. Osgood, M.D., Lieutenant-Colonel M.C., U.S.A., instructor in surgery and in orthopedic surgery, Harvard Medical School.

He declares "that the diagnosis of hysterical spine should rarely be made; that the diagnosis of railroad spine means nothing; that the diagnosis of functional spine is usually a confession of our ignorance of the true cause of the trouble. My experience in medico-legal cases is not extensive, but it is large enough to have made me blush for the surgeon who contents himself with the diagnosis of sciatica or lumbago or functional spine, the nature of which neither the patient, the jury, nor the surgeon himself can understand."

Colonel Osgood's discussion bears the title, "Back Strain—An Accident or a Disease." It is the paper read by him before the fourth annual convention of the American Association of Industrial Physicians and Surgeons, at Atlantic City, June 9th. The July issue contains a statistical study by Austin D. Reiley, assistant inspector of risks, the Mutual Life Insurance Company of New York City, entitled, "The Problem of Ascertaining the Actual Rise in Mortality Caused by Unhealthy Trades."

H. R. M. Landis, M.D., assistant professor of medicine, of the Medical School of the University of Pennsylvania, and director of the medical and sociological departments, Henry Phipps Institute, Philadelphia, writes on "The Pathological and Clinical Manifestations Following the Inhalation of Dust."

F. Smyth, M.D., Dr.Ph., presents the results of studies carried on in the laboratory of hygiene of the University of Pennsylvania in "A Critical Review of Methods for the Study of Dust Content of Air."

Dr. John J. Moorhead, associate professor of surgery

of the New York Post-Graduate Medical School and Hospital, formerly Lieutenant-Colonel in the Medical Corps of the army, is the author of an article entitled, "Is War-Time Surgery Applicable to Industrial Surgery?"

The department of book reviews and abstracts of current literature contains a comprehensive digest of the current literature in the publications in the fields of health, medicine, research, industry, and the social sciences.

STUDIES OF THE MEDICAL AND SURGICAL CARE OF INDUSTRIAL WORKERS

"Industrial medicine," says Dr. Selby in *Public Health Bulletin* No. 99, 1919, reporting a comparative study of the medical service rendered in 170 industrial establishments, "may be defined as the theory and practice of medicine applied to the purpose of preventing and alleviating sickness and injury among industrial workers in order that they may enjoy the benefits of continuous and productive employment." It is an outgrowth of the necessities of business and "although fundamentally the science of medicine, the position which industrial medicine occupies is similar to that of employment, safety, and compensation." All are specialties of industrial management.

The reluctance of the average physician to accept this materialistic view has hampered its development. In making the necessary compromise physicians should note that, to be of the greatest usefulness, medical service in industry must benefit primarily the working people and that the limitations of its activities are set only by the initiative and resourcefulness of the man who directs the work.

Nor is this materialistic view of necessity a detriment to the development of industrial medicine, for its success hinges upon filling the logical needs of business; and the methods, system, and correlation necessary all make for the most thorough work, and for the effectual application of the principles of preventive medicine.

Much indefinite material has been published relating to the functions of industrial medicine, and certain features of such service are emphasized in which even a cursory survey of the work being done indicates that there is little uniformity of practice. Some of the most talked of features are not generally undertaken, or are carried out spasmodically. The extent of such service is greatly at variance, partly because industrial medicine itself has not been standardized.

This study is based upon the service rendered in 170 industrial establishments in the eastern and middle western states, and the percentages are drawn from 155 establishments which lent themselves to definite analysis. Comparisons for the purpose of standardization are possible from this report. Salaries paid, the personnel required, specifications as to installations, equipment, with schedules of prices, etc., all of the most practical value, are given.

The extent of the service rendered, and the nature of the work undertaken depend upon the department to which the medical service is answerable. If appended from the welfare department, routine physical examinations, prophylactic measures, the care of illnesses, recreation, education, and advancement may come within the range of its activities. If an adjunct of the compensation department, its attention will be centered upon safety measures and the care of injuries. If aid in employment is the object, trade and temperamental tests may be emphasized. In any case, the man in charge has need of adaptability, capacity for administration, initiative, and interest in the

work to make it of the best usefulness to the group served.

It appears from these studies that an establishment employing from 200 to 500 people is warranted in having a dispensary and in employing a whole-time physician. While it appears that one physician can care for larger numbers of people in groups, it is also to be observed that slight provision for medical care in larger establishments simply indicates that only injuries are being cared for. Usually the employment of whole-time men broadens the service given. The percentage of whole-time men taking care of major injuries is 51; while 82 per cent of the part-time men,—usually specialists detailed for certain work,—handle major injuries. Minor complaints are treated by 94 per cent of the whole-time physicians, and by only 82 per cent of the part-time men; 4 per cent of the whole-time men treat serious as well as minor ailments; 15 per cent of the establishments have laboratories.

There is much talk about physical examination for adaptation to work, but this function was filled by only 45 per cent of the institutions studied; 17, 1.1 per cent, had regular sanitary inspection of properties, 4 had irregular inspection, and 6 inspected only on request or complaint. Much is to be desired both as to the functions of such departments and as to administration. The best field seems to be in the way of preventive medicine, and the best efficiency in cooperation and the proper correlation with the other departments of the business. It is coming to be required by the heads of the business because of its manifest usefulness, and to be appreciated and utilized by the men. Certain standards have been evolved, but many others need to be the subject of observation and study.

A complete set of the necessary forms for records are given in this study, and a cooperative medical service for small industrial establishments is outlined. Recommendations are made of the outstanding needs, one of the chief of such needs being provisions whereby industrial managements may be enabled to procure industrially trained physcians, sanitarians, and nurses for service in their medical departments.

RESPIRATORY DISEASES AMONG CLOTH SPONGERS

The cloth sponging industry in New York has been the subject of an investigation by the New York State Industrial Commission to determine the health hazard to the workers. The *Monthly Labor Review* of the United States Department of Labor, summarizes the results of investigations in ninety establishments and describes the method that has been found most practicable in removing the causes of respiratory and other diseases in the industry. The use of steam for shrinking textile products, and the excess humidity combined with high temperatures, caused by the process, produce atmospheric conditions that are said to explain the frequency of pulmonary tuberculosis and other respiratory diseases in the trade. By the use of fans and hoods for collecting the steam which rises from the machines, nearly normal atmospheric conditions are obtainable.

DRAFT BOARDS REJECT 3,411 NEW YORKERS FOR TUBERCULOSIS

The Tuberculosis Committee of the State Aid Association of New York has gathered the names and addresses of 3,411 men who were called from that state in the draft, but were rejected for military service by the local draft boards because of tuberculosis. In connection with the

opening of clinics in thirty-four counties of the state to care for the great number of tuberculosis patients reported during the war, among whom were many former soldiers, the rejected men will be given attention and treatment as a part of the crusade against the disease. The Association is experiencing some difficulty in locating all of the men, since two years have elapsed between the time of their examination by the draft board and the present.

LEAD POISONING AMONG PAINTERS

Although a large percentage of occupational disease is known to exist among painters, inquiries reveal that very rarely does a painter suffering from the ill effects of sickness produced by lead, turpentine, benzin or other volatile chemicals used in the painters' trade, visit a physician.

Dr. Louis I. Harris, director of the Bureau of Preventable Diseases, Department of Health of New York City, calls attention to the negligence of painters in seeking medical advice in cases of lead poisoning or respiratory affections, caused by the materials of their work. He reviews the clinical studies of 402 painters who presented themselves for examination at occupational clinics of the Division of Industrial Hygiene of New York City, upon the solicitation of the health authorities and the Brotherhood of Painters. No attempt was made to group the men under classifications by age and other headings, but the 402 subjects were considered typical of the trade.

Among the 402 painters examined in the course of this study there were found 163 active cases of lead poisoning—a rate of prevalence of 40 per cent. All of these showed definite clinical signs of plumbism; 72 or 44 per cent of the active cases of lead poisoning among these painters were found to have lead in the urine in addition to clinical evidence. According to Oliver's viewpoint as to latent or potential plumbism, there were thirty-five or 8.7 per cent of the total number examined who were found to have lead in their urine, without manifest clinical signs. In other words, nearly one-half of all the painters examined, or 48.7 per cent to be more exact, gave evidence of active or latent lead poisoning.

About 70 per cent of those examined were active cases of lead poisoning or gave a history of at least one, and often many attacks of severe disorders and frequency in the appearance of intoxication produced by the poisonous substances. There were 142 painters who gave histories of recent severe intoxication in which were noted the various symptoms of weakness, nervousness, and respiratory troubles and lead in the urine.

These spells of sickness were often accompanied by weakness and dizziness which caused falling from scaffolds or ladders and similar mishaps. Most of the men were certain that more discomfort and illness by benzin than by lead, turpentine, or other volatile elements.

A tabulation of 402 cases according to the number of years in which the subjects had been engaged in the occupation showed that a comparatively small number survive as active members of the trade after having attained the age of fifty years. Also, 64 per cent of the active cases of lead poisoning occurred between the ages of thirty and forty-nine years, whereas seventy-one, or 45 per cent of all those who apparently were free from symptoms of plumbism, were less than thirty years of age. Taken in connection with the fact that most painters enter the trade before their twentieth year, and, being skilled workers, follow it the rest of their lives, and

furthermore, that of the 109 who were more than forty years of age, 59 per cent were found to be suffering from active or latent plumbism, it seems fair to conclude that the action of lead is slow in asserting itself, but that less than half who have passed the age of forty escape the disease.

The analysis of the sixty-three negative cases in which the patient had been engaged in the painters' trade for a period of ten to nineteen years shows that most of them had followed the work for less than twelve years. The conclusion is derived, therefore, that the heaviest evidence of lead poisoning is found among those who have worked as painters for ten years or longer. This conclusion is supported by the fact that 31 per cent of all the men examined who had been painters for ten years or longer were active cases of lead poisoning, while 8 per cent were latent cases. Alcoholic indulgence did not appear to be important as a predisposing factor.

It is known that to drink a glass of milk at breakfast before starting work, is an excellent preventive precaution. On the other hand, many of the men were unfamiliar with the fact that a moderate-size breakfast of albuminous food, particularly milk, puts the stomach in a condition relatively free from acid which would act as a solvent of lead dust that might be swallowed during the work.

By questioning the men as to their personal habits in handling their food while at work, in washing their hands, keeping their clothes free from lead dust and working in properly ventilated rooms, it was found that the majority habitually commit thoughtless practices which predispose to lead poisoning. Other things which seem to be means of carrying lead dust into the system are the chewing of gum or tobacco, mustaches, dusty clothes, and lack of locker facilities. Other detrimental practices of the trade among the interior painters (most of those examined were interior painters) is that of shutting up a room in which the painting is going on, so as to prevent too rapid evaporation of the highly volatile benzine and other petroleum spirits in the paint. The symptoms of lead poisoning most often reported were colic, constipation, headache and other nervous symptoms, the presence of the blue line or Burtonian line on the gums, granular or basophilic degeneration of red blood cells, anemia, arteriosclerosis, heart affections and nephritis, backache, loss of weight and muscular strength, digestive disturbances, arthralgias and so-called rheumatism, pain in the chest, metallic taste in the mouth, and respiratory affections.

More than one-fourth of all painters examined—ninety-eight—gave histories and physical evidence of chronic bronchitis and fifty-eight of them were found among those who showed evidence of active plumbism.

Ninety painters had a fairly marked pyorrhea alveolaris, and 101 showed marked decay of the teeth and lack of care, making a total of 194 or about 48 per cent of all who were examined. Only marked defects of vision were noted. Fifty-one such cases were found. Ophthalmoscopic examinations were not made. Chronic pharyngitis was found in 127 painters. Hypertrophic rhinitis was reported in twenty-eight cases, and marked deviation of the septum in 147 painters. In only fifteen was marked hypertrophy of tonsillar tissue found. Forty-two men had varicose veins and seventy-two showed marked flat foot.

Dr. Harris recommends that remedial measures be divided in two general classes: first, public health measures; second, personal hygiene. Regarding public health activities he writes as follows:

"Public health authorities can never cope with the problem of prevention in any particular field unless full information is obtained as to the extent and prevalence of a given disease and of all circumstances which predispose to its occurrence. Just as it is essential for success in the prevention of typhoid fever to have complete reports of all cases occurring in the community, in order to be able to ascertain what possible sources of infection may have caused any particular group of cases, so is it essential, above all things else, not only that physicians shall be held legally responsible for the reporting of all cases of lead poisoning that come to their professional notice, but that employers, large and small, should be required by law to keep a register of all cases of occupational diseases and of accidents resulting from work, which occur among their employees. If, by a system of factory inspection and adequate penalties, such a law were enforced, the frequency of such diseases would become fully known to the public health authorities. The particular processes or employments in which such diseases occurred could be definitely ascertained and the proper measures could then be instituted for the elimination of the factors causing such diseases."

"Aside from such a general measure of control, the following specific provisions should be enacted:

"(1.) The mixing of dry lead pigments with oils or paints, while not a frequent source of danger, should not be permitted except when proper provision for the efficient removal of lead dust that may be generated in the process, has been made.

"(2.) Dry sandpapering should be prohibited; the use of pumice stone and water, or sandpaper moistened with one of the cheap mineral oils having a low flash-point, should be made mandatory.

"(3.) When chipping off paint, or the removal of paint by the use of acetone, wood alcohol, benzine, benzol or other volatile poisonous agent is employed, protective clothes and gloves of suitable character, kept in good repair, should be provided by the employer. If this work is done in confined or enclosed spaces, adequate means for ventilation should be provided. The enforced use of gloves in painting, and also in removing paint, would be an ideal measure of prevention, because it is through soiled fingers more largely than through any other source that poison is introduced into the body.

"An educational campaign would be necessary among painters to prevail on them to use gloves if their provision was made mandatory. In an inquiry that was conducted among a limited number of painters it was found that about 40 per cent did not take kindly to the idea of wearing gloves, though this is entirely practicable for most forms of work.

"Lockers or other adequate provision for the protection of street clothes from contamination by lead dust should be made mandatory on all jobs, small or big, whether done in a shop or carried on in apartments. Overalls should be provided; keeping them in good repair and clean is a matter of personal hygiene for which special educational effort would be required. Free access to toilets should be guaranteed to every employee, whether work is to be carried on in buildings which are in process of construction, or elsewhere. Washing facilities and especially hot water, nail brush, soap and towels, should be provided by every employer. Many painters who today use turpentine for this purpose because of lack of hot water and other necessities, would gladly avail themselves of such facilities; and that minority which is indifferent to the use of this most important protective measure could be induced to adopt the habit through educational effort.

"Lunch-room provision in a place apart from shops or apartments in which painting is done or in which lead pigments are mixed, should be provided on all jobs."

"Drop cloths should be frequently changed or washed."

The author discusses the desirability of substituting zinc for lead and the need of labeling poisonous agents. Then he comments on compensation under state laws as follows: "Compensation for occupational diseases and for occupational lead poisoning in particular, will do more to safeguard the health and lives of workers than any other single legal or hygienic measure. It should not be delayed."

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C. E. A. WINSLOW, DR. P. H., *Editor*

THE HEALTH CENTER MOVEMENT

THE most striking and typical development of the public health movement of the present day is the health center. As is always the case with a tendency that is in the scientific "fashion," the term is used to describe many more or less widely different enterprises. The Philadelphia Health Center, which was really a health center in its inception has now become little more than an infant welfare station. The health centers established several years ago by the New York City Department of Health were experiments in the decentralization of local health administration; while, on the other hand, the health centers established by the nurses of Henry Street are practically local nursing centers without any official status at all.

At present, however, there is a tendency to visualize the potentialities of the health center on a wider and more comprehensive scale. The Cincinnati Social Unit plan, with its primary emphasis on health, offers perhaps the best example of the health center extant; but the county of Oakland, California, is planning a county health center of a most ambitious type and public health agencies in the city of Boston have under consideration a plan for health cooperation which may ultimately create something in the nature of a principal health center for an entire city.

What is a health center? And when may any sort of local health organization for health betterment be properly entitled to the designation?

There are at least two broad aims which may perhaps be considered as essential features in any plan which can fairly claim the title of a "Health Center." The first of these aims is the provision for a definite, limited locality of a fairly complete machinery for health protection of all kinds. An infant welfare station alone, a nursing center alone is hardly a health center; for the essence of the whole plan is a sanitary background of the highest possible character. There must be

special concentration of physicians and nurses for school inspection within the district. There must be an infant welfare station, a tuberculosis clinic, and a venereal disease clinic in the area, and preferably at the headquarters of the center itself. There must be adequate visiting nurse service—at least one nurse for each 2,000 population, besides the school nurses—and preferably somewhat more. All these agencies whether public or private must be coordinated under a local district organization.

In addition to the correlation and intensification of such normal health activities as those cited above it is highly desirable that the health center should furnish certain other services not now generally available. First and foremost of these desirable new facilities is a diagnostic clinic. One of the most fundamental aims of the modern public health campaign is the detection and treatment of disease in its incipient stages and a diagnostic clinic, at which preliminary examinations may be made and from which patients may be referred to their family physicians or to existing dispensaries and hospitals, should prove an invaluable part of a program for intensive local health improvement.

In addition to the development of complete machinery for health preservation there is a second aim which is an equally essential part of the health center plan. This is the mobilization of local public sentiment within the district for the support of the health movement. In the Cincinnati plan this has been very thoroughly provided for by the organization of a sort of two-chambered legislature for the district, the upper house composed of representatives of various local professional groups, such as clergymen, journalists, physicians, lawyers, nurses, social workers, etc.; the lower house made up of local group captains, one from each block or other definite area within the whole district served by the health center.

Through an organization of this sort it is possible to conduct health propaganda which will be

really effective and to secure an interest in the aims of the center and an attendance at clinics of various sorts which no other kind of effort could possibly secure. Furthermore, it creates within the district the germ of a local health consciousness which will help to carry on the work long after special outside stimulation has been removed. This must be the ultimate aim of every vital health movement; for health will be effectively conserved in the long run only in communities where the average citizen appreciates the value and the necessity of health conservation as he appreciates the value and necessity of education at the present time.

EDITOR.

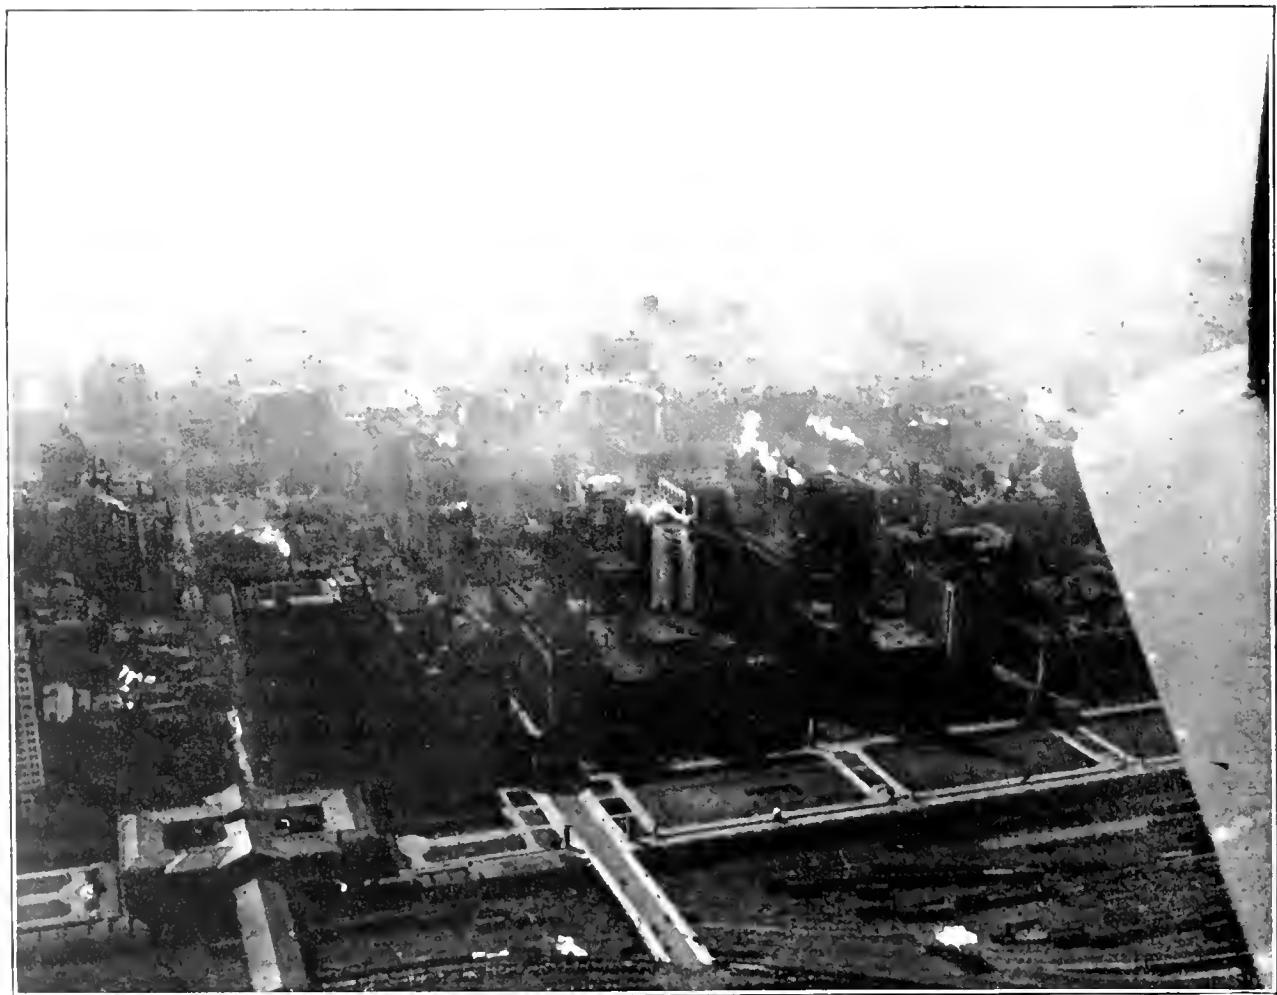

"What physical and mental overstrain, and underpay and underfeeding are doing for the race in occasioning infant mortality, a low birthrate,

and race degeneration, in increasing nervous disorders and furthering a general predisposition to disease, is appalling. These are the problems which require first consideration, if decadence is not to be the fate of industrial communities."—W. L. Mackenzie King.—"Industry and Humanity."

NARCOTIC DRUG ADDICTION A DISEASE

The attitude of the medical profession and the public, which assign drug addicts to the class of the socially outlawed and the criminal groups, is declared unjust and mistaken by Dr. Ernest S. Bishop, medical criminal professor of medicine, New York Polyclinic Medical School and Hospital, New York City. In an article on narcotic drug addiction and public health problems, published in *The American Journal of Public Health*, July, 1919, he insists that drug addicts are sick men and should receive treatment instead of being sent to jail. He advises a change in legislation intended for remedial purposes.

A FOREST OF SMOKE STACKS

SMOKE FRUSTRATES PHOTOGRAPHER.—American cities suffered excessively from the smoke nuisance during the war. The demand for coal to supply the navy and American shipping diverted the better grades of hard coal and anthracite to the seaboard, and bituminous coal and other smoke-producing, inferior grades of coal, were substituted in heating and power plants wherever possible. Chicago became a smokier, dirtier city because of the substituting of poorer grades of coal. The photograph shows the curtain of smoke which hangs over the business center or "Loop" district of Chicago. Half a million persons who are employed in the loop spend their working hours in an atmosphere so dense on many days that buildings cannot be distinguished even in outline at a distance of six blocks. The photograph was snapped from an aeroplane at a point directly above the shoreline of Lake Michigan. Because of the smoke-laden atmosphere, the buildings and streets one mile westward are indiscernible.

THE PLANS AND PURPOSES OF THE AMERICAN PUBLIC HEALTH ASSOCIATION

BY LEE K. FRANKEL, THIRD VICE-PRESIDENT, METROPOLITAN LIFE INSURANCE COMPANY, NEW YORK CITY, PRESIDENT, THE AMERICAN PUBLIC HEALTH ASSOCIATION

THE older members of the American Public Health Association who have followed its financial fortunes for years must be distinctly gratified at the fact that for the first time in its history the Association is not carrying a deficit but has a surplus in the treasury and is now in a position to carry out a program of activity which was formulated several years ago. The need of such a program is best indicated by a survey made by the writer last summer to determine the present status of health officers in the United States. A questionnaire sent out to the more important local and state health officials in the United States and Canada brought replies from 417. A study of these showed that 60 per cent received under \$25 per week. Only 36.7 per cent were full-time health officers and of these 25 per cent received less than \$25 per week. The average salary for the entire group was \$1,383 *per year*. Out of the 417 officers only eighty-six were appointed under civil service rule; forty were appointed for indefinite terms; 50 per cent of all the men were appointed for less than two years.

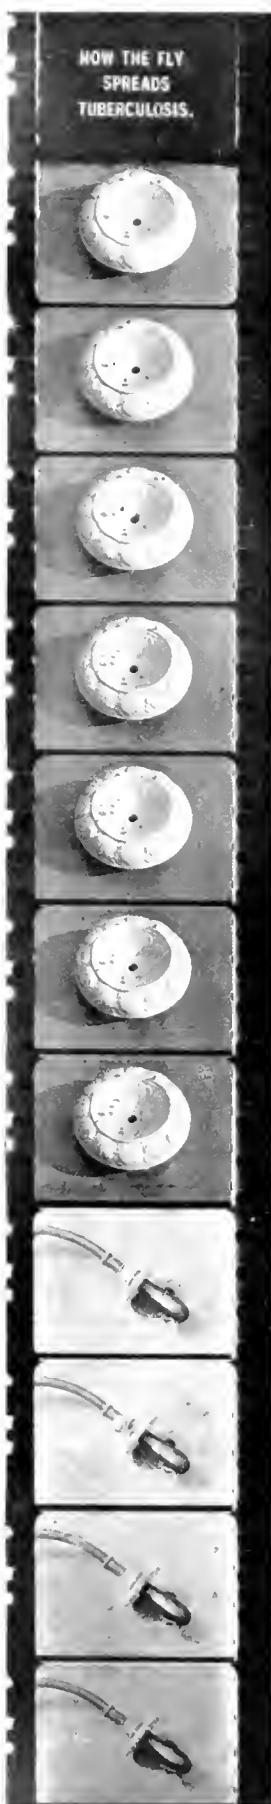

It is no exaggeration to say that owing to the apathy towards health matters no city makes adequate provision for its health department. In certain communities, the *per capita* is as low as eight cents as compared with \$2 *per capita* for the fire department. Inadequate salaries are paid to health officers. In too many instances the health department is the football of politicians. Health officers only too frequently have little or no technical knowledge and experience. The greatest asset which men have and without which their possessions are worthless, good health, is subordinated to other interests.

It is the irony of the situation that, notwithstanding the apathy and indifference of the public, its law-makers, and its legislators, there should have been a marked improvement in morbidity and mortality in the last thirty or forty years. I need not cite statistics here. The reductions in the death rates for typhoid fever, yellow fever, smallpox, diphtheria, tuberculosis, and other diseases are well known. These reductions have been accomplished by the enthusiastic and hard-working health officials, notwithstanding the difficulties that have been thrown in their way.

With this thought in mind, the program of the American Public Health Association contemplates the following: (1) preparation of standard forms and standardized literature for health officers; (2) procuring legislation providing for full-time local and state health officers; (3) procuring adequate appropriations for health work; (4) developing of a better *esprit de corps* among health workers; (5) meetings and conferences at which all organizations interested in better health may be represented; (6) conducting an employment bureau for health officials; (7) conducting an information bureau of health matters for members and others; (8) organization of local and state health associations; (9) coordination of national and state organizations engaged in health activities; (10) publication of a technical health magazine for education of health officials, the *American Journal of Public Health*; (11) publication of a popular health magazine which should interpret the scientific knowledge regarding disease in terms of popular understanding; (12) campaign of popular health education that will reach every citizen in the community.

That this program is an ambitious one, no one can gainsay. It is a feasible one, however, and can readily be accomplished if the sinews of war are given to the organization. The recent remarkable increase in membership, now approaching one thousand, shows very clearly that the membership of the Association is enthusiastically interested in its welfare and that the cooperation of the members can be depended upon to further the purposes and aims of the Association. It is hoped that by the time of the annual meeting of the Association in New Orleans in October next, 1,500 new members will have been added to the membership roll.

Following a suggestion made by Dr. George E. Vincent regarding better team-play in health work, at a recent meeting held in New York City a national health council was formed in which, for the present, there are represented eighteen national associations interested to a greater or less extent in public health movements. It is believed that this new council will be the nucleus for a better coordination of health work in the United States.

MOTION PICTURES IN PUBLIC HEALTH

BY LESLIE WILLIS SPRAGUE, DIRECTOR, INDUSTRIAL SERVICE SECTION, COMMUNITY MOTION PICTURE BUREAU, NEW YORK CITY*

IT is not too much to say that motion pictures have possibilities in the line of promoting public and private health, not exceeded by their very evident recreational powers. Up to the present time theaters have magnified their entertainment potency, but the promise is that in the near future other agencies than the theater will demonstrate their value for various educational campaigns, including public health as one of the most important.

Already motion pictures have proved effective in public health service, having received special consideration at the hands of many health experts and public health organizations. A large and increasing collection of general health films is available for use in educational, recreational, and propaganda work. Health organizations, corporations, some municipalities, several states, and the Federal Government have all produced films which present various aspects of health. Subjects ranging from the danger of the house fly and the mosquito to insanitary conditions and methods of combating such plagues as typhoid and infantile paralysis have been filmed. There lie before me as I write several lists of motion picture subjects dealing with various phases of public and private health. Sanitation and contagion are themes presented. Fatigue and rest have been considered. Nursing, dentistry, tuberculosis, pure food, and pure milk, are well illustrated.

Films Stimulate Sanitary Reforms

These and other health films have been used by many organizations in various ways to promote the interests of public health. One of the states

has produced motion pictures which presented the work of various state institutions for the purpose of informing its citizens concerning the need of those institutions. These films projected in many communities of the state resulted in arousing public opinion through effective information and bringing influence to bear upon the legislature which provided immediate and generous appropriations in behalf of the institutions of the state. In a southern city where insanitary conditions were found to be a public peril, the motion picture was pressed into service and pictures were taken and presented showing the dangerous conditions. The result of this effort was a speedy and general reform.

A considerable use has been made of motion pictures in many communities to permit private cooperation with public health agencies in combating the evils of impure milk and the house fly, contagious diseases, and insanitary conditions generally.

A number of large corporations have produced and used motion pictures to encourage interest in and a knowledge of health matters. While relating primarily to industrial health, concerning which a later article in this magazine will deal, these motion pictures include many other matters of public health. They have proved their usefulness in promoting a general interest in health matters.

Hospital Exhibits Health Films

The success of a week's health campaign conducted recently with the aid of motion pictures by a leading hospital is worthy of special mention. Daily and varied programs of motion pictures were projected in connection with meetings in behalf of the work of this hospital. These programs included such subjects as street clean-

*The first of a series of three illustrated articles by Leslie Willis Sprague describing the use of the motion picture in promoting interest in public health. The series includes articles on the following subjects: (1) "The Motion Picture in Public Health"; (2) "The Motion Picture in Industrial Medicine"; (3) "The Motion Picture in Social Medicine."

ing, fighting patent medicine, pasteurizing of milk as a protection against typhoid, public baths, rest periods, insanitary kitchens and food, proper care of the body in health, better babies, children's recreation, sex hygiene, tuberculosis, and other contagious diseases. The chief of the hospital gives hearty testimony about the gratifying result of these programs.

Although there are important subjects concerning public health easily capable of being filmed which have not yet been treated and although there is much room for improvement upon some of the health films already made, there is now available a sufficient library of films on health subjects to enable any agency to apply the motion picture to the needed task of awakening the public to a generous participation in the interests of health.

Two things are clearly to be done by motion pictures in this connection: first, to interest the people generally in matters of public health; secondly, to give the public definite information regarding important reforms in matters which from a health point of view concern the community and every citizen.

Subjects That Films Will Touch

Under subjects of general interest the motion picture is capable of presenting appealingly facts relating to the care and caution which must be shown by all citizens in order to observe necessary sanitary rules and to keep themselves in proper health.

Under subjects of needed reform in public health the motion picture will be effective in promoting and dominating public opinion, and through an awakened public opinion secure necessary appropriations for the furtherance of general health.

Where and how to use motion pictures for public health purposes are questions which must be answered by and for each community in accordance with local conditions. A motion picture theater is often available for special programs of general community interest. Health films are often shown by theaters in connection with their recreational programs. For the desired result, however, a wise plan is, using of the theater to present a full program in the interest of some specific health need, and to invite the citizens to view the pictures without charge. Brief addresses by health experts will give an added interest and effectiveness to the films that are shown.

In communities where there is no motion picture theater available for health propaganda, it

is always possible to use a church, a school auditorium, or a hall—even the streets—for the projection of health programs. Not the least effective means of reaching the particular elements of a community most in need of an awakened interest is found to be the projection of rightly organized health programs in parks or streets where the many congregate on summer evenings.

By a combination of these and other means, it is not impossible with

motion pictures to bring to the citizens of any community health interests of timely vital importance.

On the basis of results achieved, one may with certainty declare that motion pictures offer larger returns in health publicity and popular education than any other investment of time, effort, and modest means. This is particularly true in all matters where private cooperation is necessary to make effective public health regulations and undertakings.

DEFICIENCIES IN PUBLIC SCHOOL BUILDINGS ENDANGER HEALTH

IN MILWAUKEE at the June meeting of the National Education Association, Section in School Hygiene, Frank Irving Cooper, architect of Boston, chairman on Schoolhouse Standardization and Planning, spoke about the problems in hygiene involved in schoolhouse construction. It was a story of unscientific, uncoordinated work, in school buildings planned without much knowledge of principles, and developed in each section without much reference to the experience of other sections.

Mr. Cooper described the important relationships of the school building to the health of the pupil. He called attention to the necessity of clean, airy, well lighted structures, which will create an atmosphere of healthfulness and cheer, which must influence every thought and word of the child in this, the formative period of his life.

A very striking discrepancy was pointed out in the lack of uniformity in ventilation methods. Here there are standards that skilled men are planning, yet the various states are wide apart in their legal requirements and farther apart in the actual provision made. It is true that the states that have paid attention to the matter at all have adopted practically the same requirement for the number of cubic feet of air furnished, but no consideration has been paid to the efficiency of different systems of ventilation, and apparently little to en-

sure construction up to the standard. Massachusetts sets the pace, and the duct area—which may be taken for a general measure of the amount of ventilation—is from 3 to 6 per cent of the total floor area.

He spoke further concerning the surprising lack of rooms providing modern hygienic conditions. In 122 of the school buildings tabulated by his committee, sixteen have no provision for special rooms for women teachers, emergency rooms, rooms for physicians; forty buildings have a room for the teachers, but lack the other requirements, and only eighteen school buildings have a room for the school physician.

"In no department of the school building," said Mr. Cooper, in touching upon another general lack of hygienic consideration in school buildings, "is there less uniformity than in that pertaining to sanitation. Most large cities have regulations, but the larger political divisions, the states, have not realized the terrible significance of the lack of direct control over adequate arrangements for the privacy of the school children."

In illustration of some of the conditions that exist, he cited the figures secured by his committee with reference to the lighting of existing school rooms. Great irregularities have been found in this vital feature, rooms presenting intense lighting near the windows and comparative darkness back in the room.

PUBLIC HEALTH EDUCATION

BY BENZION LIBER, M.D., D.P.H., NEW YORK CITY*

IT seems to me that in the United States there are more popular health periodicals of all kinds than in any other country in the world. Probably Germany and England follow us closely in this respect. France has a much smaller number of such papers because her population as a whole has more complete reliance on the regular medical profession and also because it is less eager to learn facts concerning its health. As a consequence of this we see that the Frenchmen are those who suffer from the most ridiculous fear of fresh air, while the Germans and especially the Englishmen and Americans enjoy fresh air life indoors and outdoors much more than the Frenchmen. No doubt it is due to the many popular health writings and health talks that America is less alcoholized than most of the European countries.

Every day the necessity of popular health publications and their influence upon the public increases in this country and the time is not far when all our public health authorities will have to use health literature more extensively than they do to-day, in order to prepare the people under their jurisdiction for all the new measures they will see fit to take. Our health authorities have already felt the need and the importance of education and in this respect they are perhaps a degree in advance of the medical profession at large, which is not yet ready to talk a plain language to the plain people.

Educational Efforts Inadequate

But are the present educational efforts of the public health authorities satisfactory? And can we content ourselves with the private health papers in existence to-day?

The latter are of two kinds. There are those which are meant to attract the attention of the public to a certain healer or to a certain drug. They are the most misleading, obnoxious, and

Intelligent men perceive that the success of preventive measures in promoting the public health will come as a result of securing the confidence of the public.

The public health officer therefore seeks to collaborate with the people whom he serves, knowing that he cannot impose sanitary principles upon them by force from above.

The time is not far off when all public health authorities will find it necessary to use health literature more extensively than they do to-day, in order to prepare the people under their jurisdiction for the new measures they will see fit to introduce.

dangerous publications, and the best way to counteract their evil influence is through other publications of the intelligent, impersonal, and honest kind. The other type is the sincere, well meant journal, published by an individual or by an organization. As a rule its greatest and most characteristic mistake is its one-sidedness, as it usually represents one theory and only one, one school of healing and only one, or

one fad and only one. While that sort of literature has some advantages and has contributed largely to the enlightenment of the people, it also has great disadvantages and is often directly harmful.

That the right kind of education in health matters through the medium of literature must be effective and must constitute a great help to the health authorities and to the public, is easy to understand. It is one of those truths which are not in need of many proofs, but, although in such questions we cannot measure the results except by the opinions of those informed, we may gather some facts that are sufficiently convincing.

Dr. William A. Evans, formerly health commissioner of Chicago and president of the American Public Health Association, considers popular medicine so important as not to disdain to write for one of our greatest dailies. His simple, instructive, and helpful articles are widely read and discussed. He began his series, called, "How To Keep Well," in 1911, and we find the following words in the first introductory remarks by the author:

"Much of the work now is being done by health departments. These departments are unevenly developed. They have much of the machinery needed to do the work of physical welfare and health conservation, but they are usually very weak in getting public attention. . . . Our plan is to help these departments get to the people. . . . Their work has always needed publicity and agitation to make each unit of energy count to the full."

*Formerly editor, medical department, Foreign Press Bureau, Committee on Public Information.

As to the effect of these articles it is naturally impossible to give any definite information, but here is what Dr. Evans writes me in answer to an inquiry: "I think the articles have been of great service in getting better legislation and better administration in the section served by the paper. The president of the University of Illinois once told a group of men that my articles had changed the attitude of the Illinois legislature toward medical matters; but no one can say just how much the change in the public point of view is due to the influence of my articles and how much of it is the result of the constant evolution." May we not add that, at least to a large extent, this constant evolution is also a result of educational literature?"

In the last years other writers have followed Dr. Evans in his steps and we have had medico-popular articles in a number of newspapers throughout the country.

Among the popular medical publications of a broader, not one-sided type may be mentioned the very good Italian monthly *La Parola Del Medico* in New York, founded in 1914 and edited by Dr. Diomede Petillo, and the Yiddish magazines *Unser Gesund*, (Our Health), and *Dos Ratzionale Leben* (Rational Living) both edited by the author. The latter appeared in New York from 1910 to 1917 and had a very strong educational effect among the Yiddish speaking population of this country and Canada, as shown by the thousands of letters received by the writer. One of their direct results was the great demand of medical teaching among the Jews and the necessity for every Yiddish paper to print some sort of health literature.

Health Propaganda Effectual

Many people and institutions interested in public health have recognized the value of medical literature in the propaganda of health ideas. The Life Extension Institute publishes for its members a monthly health journal "conveying information regarding the prevention of disease, the improvement of health, and the acquirement of physical fitness, and *Keep Well Bulletins* dealing with special phases of personal hygiene and right living."

One of the best proofs that education in hygiene really pays is the fact that the life insurance companies, which certainly do not waste their money on futile experiments, have found it necessary to print and spread a mass of literary material for the purpose of instructing their policyholders how to keep healthy.

In *Public Health News* published by the Department of Health of the state of New Jersey,

February, 1916, are found the following passages, in an article entitled, "The Importance of Public Health Education Revealed by the Hand of Death":

"The most significant fact concerning recent advances in public health work is the rapid development of educational activities. This is due to recognition of the fundamental principle that complete utilization of present knowledge relating to disease can be secured only through the sanction of enlightened public opinion. Further impetus is given to the development of public health educational activities by realization of the very patent fact that health authorities must look to simple measures of personal hygiene for much of the further reduction in the death rate. . . . Educational work is a very important factor in preventing the majority of the diseases that cause death, and is the only kind of work that may be performed for the prevention of many of them."

Examples of Forceful Publicity

The American Social Hygiene Association has published many pamphlets and booklets on sexual hygiene, a number of which have been used lately by the health boards of several states and by military authorities as indispensable educational material for civilians and soldiers.

The Massachusetts Society for Social Hygiene, after five years of work, has decided that its most effective efforts are educational.

Dr. Donald B. Armstrong, of Framingham, Mass., executive officer of the Community Health and Tuberculosis Demonstration of the National Association for the Study and Prevention of Tuberculosis, says: "Most of our work aimed at the discovery of tuberculosis in this community has depended for its success on special as well as general educational activities."

In one of the weekly bulletins of the New York City Department of Health is an article which speaks of the decrease in the death rate during the summer of 1916 even in the midst of the epidemic of poliomyelitis, the decrease being ascribed to the great amount of health educational work done during that summer for the prevention of poliomyelitis and, incidentally, for more hygienic measures leading to prevention of disease in babies.

Dr. H. L. K. Shaw, director of the Division of Child Hygiene, New York State Department of Health, in one of his papers, shows in the following manner the importance of educational propaganda in his line of work: "The distribution of child welfare literature by the department is of far reaching influence and value. We have prepared a baby book which is entitled, 'Your Baby

—How to Keep It Well," and this is sent to each mother as soon as her baby's birth is reported, with a letter from the Commissioner of Health. In this way about one hundred thousand of these books are distributed each year, and about the same number are distributed by the nurses at the exhibits. It was found that a large percentage of the foreign population could not read the English book, and for this reason some leaflets were published in Italian and Polish."

New Educational Methods Necessary

Among the recommendations of one of the committees of the American Association for the Study and Prevention of Infant Mortality, figures the following: "Therefore, it would seem to be the plain duty of the committee on obstetrics to the association that it should continue in every possible way its work of public education, and should attempt to devise new methods of educating the public to the paramount necessity of saving young life in this country."

Dr. J. W. Schereschewsky, in "Problems of Infant Mortality," a booklet published by the Russell Sage Foundation, claims that the "chief causes of infant mortality are poverty and ignorance," and among the specific measures to improve conditions gives the following: "Instruction in the care of infants should be part of the public school curriculum in every state." If we wish to draw the right conclusions, we must say that instruction during the years of girlhood and motherhood would have a still better effect.

The necessity of public health education was the cause of the publication of a popular health literature by various health authorities and institutions, as the Children's Bureau, the Health Education League, the Association for the Study and Prevention of Infant Mortality, the Harvard University, the University of Wisconsin, the Russell Sage Foundation, the American Medical Association, the New York Milk Committee, the Health Departments of some of the states, the United States Public Health Service, etc.

Health Instruction Inadequate

As to the typical public health education given by public health authorities, so far it is very inadequate. The isolated and superficial lecture is often delivered by an incompetent man to a handful of people. Rarely can they get a comprehensive and complete series of lectures with good demonstrations on the subject. The health boards print short bulletins which touch lightly upon a question or two, and never enlighten thoroughly the reader on any subject. The usual bulletin is intended more or less for the medical

profession, for the local newspapers, or for such men who do not need it as a source of enlightenment. It is often largely filled with official announcements and with statistical data which mean nothing to the layman. The circulars addressed to the public by some health authorities are mostly childish and, as they are never preceded nor introduced by any preparatory matter, they have very little effect. The placards and short announcements or sentences, in the form in which they are published, are insufficient or altogether useless. Here is an example of such a placard distributed by one of our best, most active, and most intelligent bureaus of public health education:

"Sunshine and fresh air,
"Work, play and rest.
"Pure food, decent homes, and living wages,
"All these are needed to bring good health."

And here is a "Healthgram" put up as a poster in the street cars of a middlewestern city:

"Sore throat? Probably diphtheria.
"Call your doctor. Antitoxin is free.
"It prevents and cures."

Would not a good article or a series of articles on these subjects be preferable?

Health News Must Interest

The articles sent by officers of the health departments to the newspapers rarely have the desired effect. Most of the people do not care to read such matter in the paper mingled with the daily news. Many of these articles are lost as the paper will not publish those stories or notes which it believes uninteresting to the readers or which might result in some financial loss, as, for instance, when the articles are in conflict with the advertisers' interest. When it does print the article, it often throws out some very vital parts; as a rule, it will give the news part, the hot, sensational portion, and will leave out everything that is serious, instructive, or educational. The health departments know that so well that they have learned to adapt themselves to the circumstances and furnish the papers only such material that they know will appeal to the editors, and even so the health authorities succeed in passing in the larger and more influential newspapers but a small part of the material. More of it is published in the small provincial or country papers, but their influence is comparatively unimportant.

So, for instance, we do not often see in the leading papers the articles sent to them weekly under the name "*Health News*" by the United States Public Health Service, articles especially edited for the press and always accompanied by a note saying expressly that "credit need not be given,"

that is, the papers may treat the articles as original ones, an advantage which the newspapers apparently do not appreciate at all or for which they do not care. The Bureau of Public Health Service had in 1917, according to a communication to the writer, 1,266 newspapers on its mailing list. "No attempt has been made to ascertain the number of newspapers which publish the Health News," but "it is believed that the majority of papers use the material contained therein from time to time." I doubt whether the majority of the papers use it; but, even if this were so, only the minority would make use of it and probably the least important of the publications, and from time to time only, which would mean that much time and money is wasted in publishing a large part of the health news. After all, why should a public health authority always have to depend upon the newspapers? Why should it not possess its own medium to reach its public?

Disease Prevention Dawns

During the last years public health work has progressed tremendously and has shown to the world the possibilities of prevention as against the cure of disease, has opened before our very eyes that era which, when developed, as it will be in the future, will represent the ideal of applied medical science.

In the "Retrospect" of "Over a Century of Health Administration in New York City," Dr. Charles F. Bolduan divides the last century, from the point of view of public health, into the following periods: (1) the period of general sanitation, up to 1860; (2) the period of quarantine enforcement, 1860 to 1880; (3) the period of applied bacteriology 1880 to 1900; (4) the period of social analysis of disease, which began in 1900, and (5) the period of personal hygiene and education, begun in 1910, the latter two being yet in a stage of development.

The Channels of Progress

In our way toward the goal we have come to that phase in which the intelligent public health official, knowing the difficulty, nay, the impossibility, of imposing by force and from above the sanitary principles, is seeking the collaboration of the people for whom he works. This is in accordance with the advancement of our democratic ideas. The public health official tries to reach the people and to gain their confidence through all the means at his disposal. He tries to reach them in their organizations, as groups with common interests, but also, and mainly, as individuals. To be able to deal with the individual and to help him prevent disease, is really the aim of every

modern public health officer who understands his duty as a faithful and devoted servant of the public. Public health work is efficient only if it is thoroughly understood by the individual citizen, if it succeeds in interesting him, if it meets with his approval.

The individual being the unit of the vast building—organized society, the health and happiness of the individual being the sense and the purpose of society, public health has no other meaning than the preservation of the health of every unit of those who compose the public. Although it is but an elementary fact, it is useful to remember from time to time that society as such is only an abstract entity; but as the individual does not live alone and must be interested in his fellow-men from whom he derives so much profit, there is a continuous interchange of benefits between the individual and society. This interdependence between the individual and society is more visible in health matters than in anything else. Indeed, there is a most intimate relation between the individual health and the public health. Everyone's health is dependent upon everybody's health and reciprocally.

Therefore, while we have social diseases, with social causes, and for which only social remedies are possible, there is room enough to improve the health of the individual, independently of the social conditions under which he lives—that is, where the causes of disease are wholly or partly individual and where individual prevention and cure are feasible.

Enlightenment Obviates Opposition

Public health work has now reached a stage where education and instruction are paramount or, better said, where they are the only hope for further progress in public health work, the only means to achieve success and efficiency in our line.

We know from the bringing up of children that to give orders without giving the reasons therefor always results in failure. It is undoubtedly the same among adults. Orders must be understood to be executed in the right way and without opposition. For that purpose a continuous education and preparation are necessary. Do we not know that the greatest difficulties of the health authorities arise from the antagonism of the public, which is due to lack of enlightenment?

For all these reasons, I am convinced that it is necessary and that it would be useful for every larger public health authority *to publish a regular, periodical, popular, and comprehensive magazine on health questions.*

I go further and say that it is even the duty of

all health authorities to do so. Such a health journal would be the most important, the most indispensable tool in their hands. Of course, it will have to avoid all the mistakes and defects of the existing health papers. It will have to be broad-minded, not one-sided; edited in a perfectly clear and simple language; never loaded with too dry material; alive to the health problems of the day; interesting; honest; and not in the service of any private interests, not even in the service of the economic interests of the medical profession. Its policy should always be to serve the people.

The health authorities in some cities have attempted to publish health periodicals, but none of these have appeared regularly for any length of time; none has been large, comprehensive, and serious enough to deserve the name "magazine." None has been spread sufficiently in order to be known by the majority of the interested citizens. The Milwaukee Health Department prints irregularly a very small publication. The Cleveland department issues a monthly paper containing eight pages. The health commissioner of Chicago edits a more or less regular weekly consisting of sixteen pages. These feeble attempts are inadequate, but they go to show that the need of such publications has been felt in various places.

Cities Should Print Health News

Who can oppose this plan of a popular health periodical published by the city? Mainly those physicians who still cling to the old, and stupid, even if sincere, opinion that it is unethical, unnecessary, or even dangerous to teach the people how to preserve their health. There is also a selfish cause for opposition against all such plans, an opposition coming from a certain irresponsible section of the medical profession whose interest it is to keep in ignorance those whom they wish to exploit as their victims. These are the reactionaries of the profession, those who vainly try to turn the wheels of progress backwards. Fortunately, the number of such enemies of public health education is decreasing and in the silent but energetic fight between them and the public health authorities which goes on in the last years, the authorities are gaining ground, as more and more members of the profession begin to understand the importance of the public health work and as the people at large commence to feel vaguely that their interests lie with the authorities.

No doubt much progress could be made in the right direction if the medical schools would teach the students public health, would emphasize the ideal of preventive medicine, the rôle of the

doctor as a teacher of the people in health questions, the fact that through the education of the public the doctor's task becomes really much easier, that through it he will be better understood and his success in healing disease will be greater, that all the relations between the private physician and the public can only gain by education. The honest doctor should know that an educated lay public is the best material to work with; he should appreciate the fact that the people would know what to expect of physicians and that at the same time it will learn to discern between the ethical physicians and the quacks of all schools which swarm around the sick.

Health Publications Aid Authorities

The proposed publication would help the authorities in all their experiments and modifications of old rules and regulations. It would give much space to child hygiene, including such subjects as the hygiene of pregnancy and childbirth, the nursing and feeding of the baby. In my opinion, it should not neglect the question of birth control, but, of course, that would depend upon the convictions of those in charge of the paper. It would have to teach sexual hygiene in all its aspects, as far as it is possible in such a publication; all about the food problems in the large cities, dietetics, the proper way to preserve foods; the evils of alcoholism and of dangerous drugs; all about communicable diseases; how to prevent tuberculosis. It would spread knowledge concerning personal hygiene, and the best way of living according to the occupations; industrial hygiene; hygiene connected with rural or semi-rural conditions; water supply; the care or disposal of waste; the fight against mosquitoes. It should interest the public in vital statistics as far as it is not too special—in birth registration, in the notification of communicable diseases—so that the public would cooperate with the health authorities instead of being hostile to them. It should publish all the announcements of lectures on health, of all the clinics of the health department, of all the movements to promote the public health. It should give the reader elementary notions on anatomy and physiology.

A Creed of Optimism

From a long experience in the question of enlightenment in health questions, I am convinced that a magazine like the one proposed here, in order to bring results, must deal more with the positive side than with the negative side of the health problems, that is, with health, rather than with disease.

While the people should know all that is neces-

sary to know about the bacterial cause of diseases, we should be careful not to scare them into bacteriophobia, a state of mind which makes more for disease and less for health.

Let our teachings be optimistic, encouraging, hope-giving, cheering,—not gloomy, pessimistic, hope-destroying. Let us make the reader love life and health and be proud of a beautiful, healthy body.

As a rule, such a journal would be sufficient for a larger city or for a state; but here and there another local magazine in the language of the largest number of the inhabitants of a section might be necessary. In greater New York, there may be needed one in English, one in Italian, and one in Yiddish.

Every larger city and every state should publish at least one popular health magazine, as there are some special problems to be dealt with everywhere. A mining center, for instance, will need, besides the usual health education, frequent articles referring to those questions which arise from its main occupation. The same is true about agricultural, industrial, and other centers. There must also be some difference between a magazine edited for mountaineers and one edited for people who live near the seashore, and whose occupation is closely related to the sea, etc.

Approximate Estimate of Cost

As to practical details, while it is not possible to lay down any fast rules, it seems to me that it is best to adopt the principle of sending the journal only to those who will ask for it. The paper should not carry any paid advertisements. As to the price, the journal should be sent to those of the community who will apply for it, at cost price. This would help defray the expenses and the people would respect it more than if they should get it free of charge. I have calculated that, according to the present high cost of printing, paper, and cuts, a magazine of ordinary size printed on paper of the usual book quality, would cost, including all the expenditures and salaries, about four cents per copy, if the copy contain ninety-six pages and have a circulation of about one hundred thousand. Of course, these figures are subject to change and they are offered only in order to give an idea to those not acquainted with publishing matters. I have had in mind the fact that the articles contributed to such a publication do not have to be paid for. Most of them will be written by men and women in the service of the health departments, and it is certain that many of our medical scientists who are able to popularize will gladly answer an invitation to collaborate.

It seems to me that it is the duty of all health

officers who specialize in public health education to convince the city or state authorities of the great advantage of an official popular health magazine. The argument that the authorities will lack the funds necessary for its publication could be answered by the suggestion to have the readers defray the expenses by paying the cost price, by yearly subscriptions or by the copy, which would amount to a very small sum. Of course, an initial amount of money will be necessary, but even that would be repaid after a short time. It should be clear to every one that money spent in such a useful way will, in the end, economize more money. And there is something that is more important than money,—the people's health. Is it not worth while for the public health authorities to have an organ which would teach the people to collaborate with them, to prevent disease, to be their own public health inspectors, to live as healthy and as clean lives as possible, and longer lives?

5,000 DISABLED MEN GET TRAINING

More than five thousand disabled ex-service men are now in training under the direction of the Federal Board for Vocational Education. Thirty per cent of those in training are preparing for some trade or industry, twenty-five per cent are taking commercial courses, fifteen per cent are training for a profession, another fifteen per cent are studying agriculture in some form, and almost as large a percentage of the men are taking general educational courses, needed for their vocational training which is to be taken later. A few are in miscellaneous courses.

FEEBLE-MINDED IN ONTARIO

Among the progressive measures which are now being considered in the Province of Ontario and elsewhere for the care of the feeble-minded, the following are cited in the thirteenth annual report of the feeble-minded in Ontario, submitted for the year 1918, by William David McPherson, provincial secretary:

(1) The registration, under proper authority, of all feeble-minded persons not being cared for in suitable institutions and the provision of suitable supervision for those who can live in the community.

(2) The provision of Auxiliary Classes in the Public and Separate Schools in large centers for the benefit of mentally defective children.

(3) Provision for the examination, where desirable, of children and adults by physicians who are experts in the diagnosis of mental defect.

(4) The development of school medical inspection, to include special supervision of Auxiliary Class work.

(5) Medical examination, where desirable, of all persons brought before juvenile and criminal courts.

(6) Mental examination by experts of all persons admitted to orphanages, refuges, industrial schools, reformatories, Houses of Refuge, prison farms, public charities and other penal, charitable or reformatory institutions, and the adoption of suitable measures for the improvement and training of such persons, according to their mental capacity.

(7) The reorganization of community work for dependent, delinquent and defective persons, especially in childhood and youth, on the basis of better knowledge of the facts in each individual case, classification, training and preparation for citizenship where possible, and care and permanent control where citizenship is not possible.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., Editor

ETERNAL VIGILANCE

ETERNAL vigilance is the price of social progress. Not one moment may the eyes of progressive leaders be lifted from their watchful task lest reactionary Bourbonism take the advantage to get in its destructive work. Time that should be spent in doing the important work of the day must be used in protecting the right to give good service.

When the foregoing applies to a great humanitarian department of the Government in its relation to the Congress of the United States, it is time to speak plainly.

During the war Congress provided wisely for the rehabilitation of disabled soldiers and sailors, and placed the responsibility for vocational rehabilitation on the Federal Board for Vocational Education. Whenever any soldier or sailor is certified to the Bureau of War Risk Insurance as having a disability amounting to 10 per cent of his capacity, he is allowed the privilege of vocation re-education under the Federal Board.

The Federal Board and its director, with a vision unsurpassed in Government circles, proceeded to do its work. That work required the charting of new fields. There was very little experience in this country to go by. There was no possible way to estimate the extent to which this service would be used. Although hampered by conflicting provisions of law, the work of the Federal Board has been one of the outstanding successes of the war efforts of this country. The Board looked at the problem in a big way and planned to meet any emergencies. The best men obtainable were selected without reference to any consideration except ability to grasp new problems and accomplish results.

Just as the time when the work was at its height, when thousands of soldiers were applying for vocational work, a small coterie of Bourbon

politicians in Congress proceeded to limit the appropriation and to curtail the organization in such a way as to disrupt the whole well-planned program. They had no knowledge of the required work or of the expense, nor of the possibilities for the welfare of the soldier. They cut the appropriation and they phrased the wording of the Act so as to limit unduly the salaries of the experts in the fourteen districts of the country.

Then something happened. The Bourbons did not seem to realize that they were dealing with the problem of the wounded soldiers for whom the people of this country have the tenderest consideration. Protest was instantaneous. President Wilson vetoed the bill and told Congress plainly its duty in the matter. A few of the more ignorant slightly awakened to their folly, tried to defend themselves by making attacks on the Board.

It was charged that the Board had no vision, and that they could not tell what the work would cost. Chairman Good of the Appropriations Committee of the House made the terrific charge that he never knew or heard of the members of the Board or the director. Senator Smoot, undaunted by the political fix into which he was trusting his party, tried to square his position by making unwarranted and untruthful charges against the Board and the director which were immediately and effectively answered.

They could not withstand the wave of resentment which swept in from every source. The bill was re-passed with the obnoxious features removed after a debate which was characterized by the most inane and foolish statements that could be imagined in a representative body.

Rehabilitation of war cripples was saved. Had it been a measure of lesser immediate appeal, the fate would probably have been otherwise. Truly, "Eternal vigilance is the price of social progress."

EDITOR.

THE NEEDLESS WASTE OF MAN POWER

BY JAMES PHINNEY MUNROE, VICE-CHAIRMAN, FEDERAL BOARD FOR VOCATIONAL EDUCATION, WASHINGTON, D. C.*

SINCE it is the fashion in these spacious days to talk in large amounts, and since no one is criticised for using such figures loosely, we do not hesitate, though, of course, without exact statistics, to declare that at least two million boys and girls reach the age of sixteen each year. With more confidence, however, because of careful consideration of the calculations required, we venture to assert that, on the average, his family, his community, and society in general have expended at least \$4,000 to bring each youth forward to this sixteenth year. Multiplying these figures, it appears that there is annually added to the national capital, taking sixteen as the average initial year of economic productiveness, the huge sum of eight billion dollars in potential manpower. The amount of material capital annually added is much greater; but this new non-human capital is static and in large part begins at once to depreciate, while that added human capital is dynamic and has within it power of almost limitless increase in productivity during a succeeding period of at least fifty years.

Child Welfare Is Economy

Moreover, the amount of potential capital added each year would be vastly greater than it is, were it not that such large numbers of boys and girls never attain to even their sixteenth year, and an enormous aggregate expenditure upon infants and children who die before reaching even the beginnings of productivity is, from the social-economic standpoint, virtually thrown away.

Consequently, a large share of "born" manpower is lost wholly to the world, and all that amount,—which we have guessed to be eight billions,—of new human capital which is actually "in being," is still only potential and much of it either comes eventually to nothing, so that the expenditures of society upon it prove to have been clear waste, or else is so mishandled or kept from proper development that it falls lamentably below even minimum efficiency.

Of all the terrible wastes which confront the world every day,—wastes of food, of water-power, of forests, of mineral resources, etc.—none is so appalling and none so needless as is this hourly throwing away of precious human power. Furthermore, while material wastes naturally bring about unnecessary privation and suffering, human waste involves not only that, but also mental and moral distresses,—the multitude of

sorrows which accompany sickness, suffering, untimely death, lives broken by inefficiency and bad habits, lives wasted as the result of an endless list of misdemeanors and crimes which, in almost every instance, are the outcome, not of sin, "original" or otherwise, but of individual ignorance, family and social inefficiency, and national indifference.

Seven Sources of Waste

There are seven main sources of this incalculable and wicked waste of human capital. They are: infant mortality; infant and child morbidity; inefficiency brought about through illness and invalidism; inefficiency due to lack of education or to want of the right kind of education; inefficiency having its origin in absence of any stimulus or of the right sort of stimulus; needless accidents and preventable disease; and failure even to salvage the more or less efficient wrecks which result from such disablement.

A layman has no right to discuss, in the presence of physicians, problems of needless mortality, or even that far greater waste due to the inefficiency which has its seat in childhood illness or malnutrition or which arises from a state of virtual invalidism due to bad sanitation and ignorance of the simplest hygiene; but it is permissible for one not in the profession to discuss the other four sources of human waste and loss.

Educate for Specific Needs

The first of these non-medical sources and the one which, next to infant mortality, claims the largest number of victims is lack of education or want of education meeting the individual's specific needs. Mere book learning is of course a minor question in the real business of education, though no one will dispute that it makes for great social waste and loss to have, as we do in America, immense numbers ignorant of English, ignorant of the "three R's," or ignorant of both. The main waste is found, however, in that far larger body of persons who have been subjected to some kind of nominal schooling but upon whom neither the school nor any other form of education has made any actual impression. So far as concerns moral understanding, mental power, and social efficiency, those millions of persons are as densely ignorant as any savage in the heart of Africa.

*Based on a paper read before the Forty-third annual meeting of the American Academy of Medicine, Atlantic City, June 9, 1919.

One of the chief reasons why there exist in the United States innumerable men and women who, from the point of view of social and economic effectiveness, are totally uneducated, is because not only the schools, but also society in general, have almost totally ignored the main foundations upon which education should be built. No one will deny that because the two most powerful, most primitive, forces in human life are hunger and desire, and that civilization has evolved through the elaborating and refining of the social processes by which it is attempted to satisfy these fundamental needs. This being the case, education should largely be predicated upon those supremely compelling forces, and should go as far as is humanly possible in preparing every boy and girl to earn intelligently and with satisfaction the best possible living, thus rationally satisfying elaborately "civilized" hunger, and in making him or her ready for the almost universal vocation of marriage, home-making and the bringing up of children, thus rationally satisfying elaborately "civilized" desire. A thorough-going study of the problems of human waste would undoubtedly reveal that the roots of all seven of the sources of loss above enumerated go down to the inefficiency of most human beings in their nominal "earning" and to their almost total ignorance concerning the fundamental responsibilities and the daily details of that universal vocation, home-making, which, as members of households and in most cases as fathers and mothers of helpless children, they have so unheedingly assumed.

Stimulate Toward Efficiency

A second enormous source of human waste, from the economic standpoint, lies in the fact that there is an almost total lack of stimulus towards efficiency in whatever vocation the individual is attempting to pursue. Most such vocations have been chosen without knowledge, are followed without interest or understanding, and are regarded as tasks to be grudgingly performed in exchange for wages quite as grudgingly paid. The war has emphasized anew the almost incredible power of a recognized and stimulating goal in bringing workers up to a high level of productivity and it has shown, by contrast, how largely absent from the ordinary vocations of life is any stimulus except the purely negative one of that starvation which is the inevitable portion of the man, too proud to beg or too honest to steal, who will not work. That starvation stimulus serves to keep every unsupported man and woman at some kind of labor; but, being negative, it tends to depress his productivity to the very low-

est level consistent with "holding his job." On the other hand, some positive stimulus, such as genuine interest in one's work, active understanding of what it is aiming to do, or a reward that can be visualized as worth working for, immensely increases the capacity for work, and through such stimulus the output of even a comparatively low grade worker can be multiplied to an astonishing degree.

Interest Increases Output

The most pressing problem in industry today is that of finding some way of greatly increasing production while at the same time reducing the hours of work and the drudgery of labor. Far from being insoluble, this happy condition can easily be brought about; for, with an effective stimulus, the output of the worker will be largely increased, the strain, both physical and mental, upon him will be correspondingly reduced and, as a result, he will find what President Eliot has so aptly called "the joy of work."

This stimulus does not necessarily take the form of money; indeed, experience seems to show that a "bonus" or other form of financial spur is largely ineffective. Really to grip a man, the stimulus must engage his interest, his innate desire for useful service, his sense of loyalty; and actual demonstration has shown that such loyalty can be aroused even in low scale workers if they are regarded as human beings susceptible to higher forms of appeal, and if their needs and interests are carefully studied from that point of view.

Accident Control by Education

A third source of appalling waste and one accompanied with peculiar suffering is found in the extensive field of preventable accident, industrial and otherwise, and of avoidable industrial disease. The solution of this problem belongs jointly to industry and to the medical profession and, happily, much study is being given the subject throughout the civilized world. It is a waste, however, that cannot be controlled—as too often we attempt to regulate evil things—by laws and ordinances. Accident prevention and the stamping out of disease can be brought about only through widespread education, both within industry itself and before working age is reached, as to the need of unceasing caution, the meaning and use of safety measures, and the sources and control of industrial disease.

A fourth great waste arises from the fact that society not only tolerates a huge toll of victims of accident and disease but has heretofore done little or nothing to restore those shattered victims to

any sort of economic efficiency. Consequently, hundreds of thousands of maimed and otherwise handicapped workers have been thrown on the industrial scrapheap, to their own distress and to the burdening of society, when adequate training might have made most of those handicapped persons perhaps even more efficient than they were before the disabling accident.

Take Stock of Human Resources

Fortunately the war greatly stimulated interest in this problem of human waste, for it compelled an actual count one by one of the number of human beings available and effective for a wide range of services. In that human accounting we were forced to acknowledge our stupid heedlessness and criminal prodigality in regard to this most precious of all resources. It is no new thing for a government, whether Federal, state, or local, to do something toward lowering the death rate—especially in infancy,—and toward preserving the public health; but never until the war brought us face to face with the necessity of getting enough trained and trainable men to meet a crucial emergency have those in authority in the United States given the heed they are now giving to this and to many other complex problems of human conservation.

Again we refrain from dealing, before physicians, with details of governmental care in matters of personal and public health except to note the broadening of its former activities, the extension of its cooperation with the health work done in states and communities and the institution of a variety of new services which cannot fail to have far-reaching influence upon the problem of reducing manhood waste.

In the field of education, the Federal Government, especially through the Bureau of Education, is taking effective steps toward assisting the states to diminish that burden of illiteracy under which all of them,—and some of them to a scandalous degree—are trying to carry on. It is also active in promoting a nation-wide campaign for Americanization as a result of which it is hoped that there will be a healthful diminution in the number of those who accept all the benefits of living in the United States without making any effort to learn the English language and without taking any steps whatever towards responsible citizenship. These activities, many of them contemplated or tentatively begun long before the war, have been quickened thereby and have found much support from quarters heretofore indifferent or even hostile to this fundamental need of American democracy.

Another pre-war educational activity of the Federal Government has been greatly forwarded by war experience in the stimulating of vocational education. In February, 1917, was passed the Vocational Education Act under which the government at Washington cooperates with the states through subsidy and in other ways in encouraging sound vocational training for youth over fourteen in agriculture, industry, commerce, and home-making. In the less than two years during which this law has been in effective operation upwards of half a million persons have been given some measure of vocational training under Federal subvention and over fifteen thousand teachers will have been trained or will be under training for vocational service. By December 30, 1917, every state had taken advantage of the law, and in most of the states the field for this type of schooling is every month extending. The effect of all this upon that type of human waste which results from lack of education, or from an education unsuited to the needs of the individual boy or girl, cannot fail to be, in a comparatively few years, most salutary.

Lack of Adjustment Remedyable

Upon the side of devising adequate stimuli for the worker, the Federal Government cannot do as much, of course, as it can in the more definite territory of education; but as a part of war service important contributions have been made in the comparatively unexplored regions of employment management, of labor turn-over, of the regulation of unemployment, and of the prevention of misunderstandings between employer and employee. Moreover, the Vocational Education Act permits of the development of sound methods for training foremen, superintendents, etc., which in time should greatly assist in getting at the real heart of this problem of waste through lack of adjustment of the worker to the conditions under which he works; but it is a development which can come only slowly and which must be accompanied, or indeed preceded, by the education of both employer and employee concerning their joint responsibilities to society and to the individual boys, girls, men, and women who, as workers, are finally the determining factors in all social growth.

Employer and employee must both be extensively educated, also, along lines of safety and hygiene if the incalculable economic and social loss through avoidable accident and preventable disease is to be done away with. Meanwhile, the Federal Government is already doing something through promoting the teaching of such subjects in the schools, and is doing and will do much more

in calling public attention to questions of conservation through its support of measures for rehabilitating those disabled in war, a support soon to be extended to those injured in the pursuits of peace.

Re-Training for Handicapped

In June, 1918, Congress passed a Vocational Rehabilitation Act making the Federal Board for Vocational Education, already in existence for the purpose of administering the Vocational Education Act, responsible for placing back in industry, directly or after adequate training or re-training, every soldier, sailor, and marine disabled in the late war under circumstances entitling him to compensation under the War Risk Insurance Act, when such handicapped men desire this kind of help. Already the meaning and purpose of this legislation have been placed personally by agents of the Federal Board before at least a hundred thousand disabled men, and already many thousand of these have been put into training or have been recommended therefor. Even in this short time the experience of this country, as well as the longer experience of our allies, has satisfactorily demonstrated that, given proper training for an occupation which not only is within his powers but appeals to his interest, almost any disabled man can be made as efficient as before his injury. Moreover, it is being shown that with the special guidance and the individual training which the Rehabilitation law provides and the peculiar stimulus which war service has given, many such disabled men can be made more efficient, and in not a few cases markedly more efficient, than they were before.

Grants in Aid to States

So fully has this work of rehabilitating disabled soldiers commended itself that the Congress is likely soon to pass legislation extending, wherever a state may cooperate in the work, Federal aid towards the rehabilitation of men and women disabled in industry by either accident or disease. Were this proposed law to be passed and to be fully availed of, the number of persons transformed from burdens upon society to active workers carrying more than their own support would mount into the hundreds of thousands.

With the demonstration of the national need for human conservation so strikingly given by the war itself, with the direct stimulus which Federal aid and subsidy always provide, and with thousands of men and women roused as never before to the gravity of this waste of man-power, it seems more than probable that the next twenty-five years will see really remarkable progress not only in direct life conservation and in indirect

conservation through raising appreciably the whole health level, but also in making life worth while by educating ever increasing numbers to understand what they are living and working for, by giving his work a real meaning to the worker, and by saving from economic disaster and personal despair millions whom we now ruthlessly consign to an existence worse than death by failing both to control industrial accident and disease and to rehabilitate their victims.

PUBLIC HEALTH SERVICE INVESTIGATES SICKNESS INSURANCE

Investigators for the United States Public Health Service have recently compiled a volume of information concerning health insurance and sick benefits among the 400 benefit associations of the United States. The data include the records of disability due to sickness and non-industrial accidents for which cash benefits were paid under the various regulations of the associations. The studies furnish an insight into the sickness experience of over 750,000 wage earners engaged in many different industries and occupations covering a period usually of three years.

General B. S. Warren, assistant surgeon, United States Public Health Service, and Edgar Sydenstricker, associate statistician, directed the inquiry. They conclude that a conservative estimate of the total amount of sickness which will require medical service under the contemplated health insurance measures in the United States, will average from eight to nine days per insured person. This estimate includes the first three days, and sicknesses lasting less than four days for which medical service would be provided, though it is not furnished at present by most of the associations, nor under the laws of states which make provision for health insurance.

A physician with 1,000 insured persons on his list might expect to have from twenty to forty constantly sick.

JOURNAL OF DENTAL RESEARCH

The *Journal of Dental Research*, in the initial number publishes valuable original papers and critical comments, among them the following: "The Genetical Factor in Dental Research," by C. B. Davenport, Ph.D., director of the Eugenics Record Office of the Carnegie Institution of Washington; a preliminary report, by Joseph Head, M.D., D.D.S., dentist to the Jefferson Hospital, Philadelphia, and C. Ross, bacteriologist, Mulford Laboratories, Philadelphia, on the "Bacteriology of Apical Abscesses." There follows a comment on the paper by I. J. Kligler, Ph.D., assistant in bacteriology, Rockefeller Institute for Medical Research, New York City; and further comment on the criticism by Kligler, by Head and Roos.

An open statement to Dr. William J. Gies, on the "Bacteriology of Initial Dental Caries, the Dental Mucin Plague, and a Proposal to Encourage Research Along These Lines, is offered by J. Leon Williams, D.D.S., New York City. Accompanying it is a reply by Doctor Gies to the statement by Doctor Williams, on the subject, "Bacteriology of Initial Dental Caries."

Several original papers are printed, and also the proceedings of the First District Dental Society of the State of New York, together with a paper read by Chalmers J. Lyons, D.D.Sc., Ann Arbor, Mich., on "Some Pathologic Conditions of the Mouth and Their Treatment."

HOUSING DEVELOPMENT AS A POST-WAR PROBLEM IN CANADA

BY THOMAS ADAMS, HOUSING AND TOWN PLANNING ADVISER TO THE CANADIAN GOVERNMENT, OTTAWA, CANADA*

Housing as a War Problem

As a war problem, housing has been discussed very fully already. The work which has been done by the British and American Governments is well known, and the Bureau of Housing and Transportation at Washington will shortly issue a report on its operations which will fully acquaint anyone with the latest information on the subject from the most authoritative source. In Canada we did not attempt to carry out any government housing during the war. That was a misfortune in one respect since it prevented the using of the energy and restlessness that come during periods of war, as a means of creating some bold experiment in model housing.

On the other hand it is our good fortune that our present position is not prejudiced by the carrying out of any extravagant and hurried scheme during the war. By extravagant, of course, I mean the necessary extravagance created by war conditions.

It Is a National Problem

Since the war ceased we have started in Canada to deal with housing as a national affair and as a problem of reconstruction. In that sense I believe the United States is still without any definite policy. In my opinion the Canadian policy in this matter is based on the soundest principles that can be applied under a federal constitution in a democratic country. Of course it is not in any sense final. It is a beginning and I am certain that if we apply proper administration it will be a beginning of very great things.

In the inauguration of an entirely new policy, involving almost revolutionary changes in sentiment and practice, it is better to begin cautiously and with moderate expectations, only making

*I commend the Canadian scheme *** as an example that might well be followed in the United States. That Government should have its Federal office of housing and town planning, a coordinating and advisory bureau. The war has been won by organization as well as by the splendor of our men. If it had gone on a few months longer you would have wasted more than you now need to spend in solving your housing problem. The Federal Government should offer a sum of money, which to be equivalent to the Canadian appropriation, would be about \$300,000,000, to assist the states to carry out housing and town planning schemes.*

sure that the principles are sound and that whatever is done is a contribution towards the complete administrative whole it is sought to attain. It is desirable also to use public enterprise as a stimulus and aid to commendable private enterprise and not as an alternative, except to questionable private enterprise.

The Canadian National Housing Project

The armistice was signed on November 11, 1918. Immediately afterwards representatives of the Federal and Provincial Governments of Canada met and, among other subjects, discussed the desirability of creating better housing conditions. It was observed that there has been a practical cessation of building operations during the war and a scarcity of housing accommodation. The Privy Council only reported on the matter on December 2, and on the following day, December 3, an Order-in-Council was issued granting a loan of \$25,000,000. On December 12, a committee of five members of the Cabinet was appointed to administer the loan. Prior to the taking of this action by the Dominion Government, the Provincial Government of Ontario had decided to appropriate \$2,000,000 for housing in Ontario as an addition to any Federal loan that might be given.

How Fund Is Administered

The Federal loan of \$25,000,000 will be distributed among the nine provinces of Canada, *pro rata* to the population. It is hoped that each province will add a contribution of its own so as to make the available total much larger. The money will be lent at 5 per cent to the provinces and will be repayable by them, in most cases, in six monthly, equal installments of principal and interest.

I will now deal briefly with the administration

*Read at the National Conference of Social Work, Atlantic City, N. J., June, 1919.

of the loan under two heads: (1) *Administrative Machinery*, and (2) *The Conditions and Principles Under Which State-Aided Housing Schemes Will Be Carried Out*.

I. Administrative Machinery

The Federal Government, the Provincial governments and the municipalities, are all involved in the machinery that has to be set up to carry out housing schemes.

Under the Constitution of Canada the duty of providing houses and controlling land development is a provincial and municipal, and not a federal matter. Many have urged that the Federal Government should itself carry out housing schemes, but this would interfere with the autonomy of both the provinces and the municipalities. For the sake of the future development of government housing and its successful administration, it is essential to pay full regard to this fact. In the working out of the administrative machinery great care has been taken to avoid anything that would have the appearance of interfering with the local government. At the same time it is obviously essential that the Federal Government should take some responsibility with regard to the way in which their money is to be used. They certainly should give some leadership and guidance on the subject and afford an opportunity for coordinating the work of the various provinces.

As we shall see later, each province, before getting the loan, has to submit a general provincial scheme of housing for the approval of the Federal Government. Some kind of Federal organization is necessary to examine these schemes, to report on them, and subsequently to exercise some oversight to see that they are carried out. All this must be done with great care and tact as a means of assisting the Provincial governments, rather than as a means of criticising anything they do. Once each provincial scheme is approved by the Federal Government, the jurisdiction in respect of all local schemes will rest with the provincial authorities. In the same way it is expected that as a rule the provincial authorities will show a similar confidence in the municipalities and that once the municipal scheme of housing is settled the municipality will be left comparatively free to administer it and to obtain such loans as it requires to be spent in conformity with the scheme.

To put it briefly, the machinery represents complete cooperation between the Federal, Provincial and Municipal governments with the responsibility divided as follows:

(a) *Federal*.—Responsibility for approval

of general schemes of each province dealing with the standards and conditions to be imposed by the province in making loans to municipalities; carrying out of advisory work in connection with provincial legislation, forms of scheme, and preparation of plans and specifications, etc., and reporting on questions relating to standardization, comparative data collected from different provinces, etc.

(b) *Provincial*.—Responsibility to repay loan to Federal Government and to administer the general scheme it has prepared and to secure from each municipality borrowing money a general municipal scheme for its own area.

(c) *Municipal*.—Responsibility for repaying loan to the province and supervising and carrying out all housing schemes in accordance with the principles and standards included in the municipal scheme which is part of, or consistent with the provincial scheme.

The result of the procedure is that the real work and the real responsibility rest with the municipality, although in many cases commissions are delegated to do the work. At any rate the responsibility is local. It is near to the people. Close observation of the working out of details will be best attained by this means. It is likely that the municipalities will be slow to accept the responsibility. This has proved to be a stumbling block to housing progress in most countries where national housing has been carried out. It is also probable that some people will fear that our municipal administrations are not competent to undertake such additional responsibilities.

Undoubtedly there are defects in our municipal councils and forms of government and we can always find good reasons for withholding the giving of any added duties or powers to our municipal administrators, but I shall hazard the statement that the longer we continue to do that the longer we shall have to wait to get local bodies in whom we can have confidence. My own opinion is that we should pile up responsibility on the municipal authority for all matters of local administration; that we should not attempt to supersede them more than is necessary for purposes of coordination and general progress, and that, even if this does produce mistakes, these mistakes will, on the whole, be less than if we attempted to centralize the machinery of the Government too much and to create new forms of bureaucracy.

The actual progress made up to the present is that a Federal office has been opened in which there are town planners, engineers, and architects engaged in collecting data, preparing reports on

different aspects of housing and town planning; preparing model plans for distribution to the provinces and municipalities; acting as a clearing house for information on all phases of the housing question; inquiring into questions of shortage of houses, etc. This office is in direct communication with the administrative departments of each of the provinces. The Order-in-Council setting out the Dominion scheme was not completed and issued until each province had an opportunity of raising objections, the result being that the Federal scheme was practically agreed to by all the provinces before it was made public. Since this Federal scheme was issued, on February 20, the following provinces have passed Acts of Parliament to take advantage of the loan and deal with the procedure necessary for that purpose: Nova Scotia, Prince Edward Island, New Brunswick, Quebec, Ontario, Manitoba, and British Columbia; leaving only two provinces which have, so far, not joined in the Government scheme, for reasons that are local and not because they object to the scheme in any principle.

Provinces Take Up Project

In four out of these seven provinces, general schemes of housing have been prepared and in the other three, schemes are in course of preparations.

In Quebec and Ontario, Directors of Housing have been appointed and steps to create special officials are being taken in the other provinces.

I am not able to enter into many details regarding the progress made, but will simply quote the latest report of the Director of Housing of the one province of Ontario, which says:

"The following 47 municipalities have passed the necessary by-laws bringing them under the provisions of 'The Ontario Housing Act, 1919.'"

CITIES	TOWNS	VILLAGES AND TOWNSHIPS ¹
Windsor	Sudbury	Port Dalhousie
Fort William	Sandwich	Madoc
Galt	Hespeler	Port Credit
St. Catharines	Ingersoll	New Toronto
Sault Ste. Marie	Oshawa	Nimitta
Ottawa	Ford City	Point Edward
Sarnia	Cochrane	Richmond Hill
Woodstock	Trenton	Fergus
London	Sturgeon Falls	Port McNicoll
Guelph	Leamington	Milverton
Niagara Falls	Palmerston	Neelin
Brantford	Perth	Brantford
	Whithby	West Oxford
	Listowel	Gloucester
	Bridgewater	
	Thorold	
	Mimico	
	Walkerville	
	Midland	
	Arthur	
	Port Colborne	

"About five hundred plans have been approved by the Director of the Bureau of Municipal Affairs, and in a considerable number of the above mentioned municipalities houses are under construction.

"The director estimates that the loans required

by these municipalities will aggregate nearly \$10,000,000.

"About twenty municipalities are considering plans for acquiring land and erecting houses on a large scale. Some of them have already purchased land."

Toronto, the largest city in the province, is not included in the above list. It is preparing a scheme of its own under special powers, and purposes to carry it out by means of municipal bonds raised for the purpose.

I would refer those who are interested in obtaining further information to the report of the Ontario Housing Committee, which contains a number of plans for use by municipalities, if desired, and also to the regulations and forms of the Ontario province, both of which publications can be obtained from Mr. J. A. Ellis, Director of Housing, Parliament Buildings, Toronto.

It will be seen from the dates mentioned and the progress already made that the process of joint cooperation of the three sets of governments does not lead to any serious delay in administration.

II. State-Aided Housing—Standards and General Principles of Schemes

In the Order-in-Council of February 20, the standards and principles of the Federal scheme were set forth. The general object was stated to be as follows: (a) To promote the erection of dwelling houses of modern character to relieve congestion of population in cities and towns; (b) to put within the reach of all workingmen, particularly returned soldiers, the opportunity of acquiring their own homes at actual cost of the building and land acquired at a fair value, thus eliminating the profits of the speculator; (c) to contribute to the general health and well-being of the community by encouraging suitable town planning and housing schemes.

Conditions to Be Complied with by Provinces

Four conditions were attached to the proposed loan as follows:

(1) The general housing scheme had to be approved as already stated. It was required that the general scheme should include a schedule of minimum standards for purpose of health, comfort, and convenience.

(2) Loans were restricted to \$3,500 for frame or veneered dwelling, and \$4,500 for dwellings of more durable construction as specified.

(3) Money could only be loaned to the

¹Since this was written the number has reached eighty.

provinces and municipalities, housing societies or companies with dividends limited to 6 per cent, and owners of lots for erecting houses for their own occupancy.

(4) The period was fixed to twenty years for local improvements such as pavements, and frame or veneered buildings; and thirty years for land and more permanent buildings. Due regard is paid to the life of the improvements with a view to encouraging more permanent construction. Thus a loan of \$3,000 for a frame dwelling for twenty years would cost about the same per month as a loan for a better house costing \$4,000 for thirty years.

These are the four conditions, but attached to the Government project are a number of recommendations with regard to standards. Some of the provinces are adopting these recommendations merely as suggestions to be made by them to the municipalities. Others are adopting them and making them compulsory, a few go further in some respects and not so far in others.

Encourage Better Housing Standards

I shall have to refer you to the Federal scheme, a copy of which I shall be pleased to forward to any applicants, for the details of the standards, and will only draw attention to a few of the outstanding points. The standards set forth are very general and do not enter into much detail. The object was to secure the things that are essential, and that are usually overlooked in municipal by-laws.

They comprise recommendations that land be acquired by a speedy method at the lowest cost; that sites be properly planned and that local improvements, sewers, and water supply, be provided in advance of the building of houses; that one-tenth of all areas for housing schemes be reserved for open spaces; that not more than one-tenth, and in no case than one-eighth, of the gross cost per dwelling be spent on bare land; that certain standards be applied to the sizes or rooms, distances between buildings, and sanitary conditions. For instance—every house should have a bathroom.

Proportion of Cost of Land to Cost of House

With regard to the suggestion that the cost of land should be fixed in proportion to the cost of the dwelling, the reference is to the land in an unimproved condition, and if pavements, sewers, and water-mains are constructed it would mean that the proportion of the site of the dwelling might be a fourth or a fifth instead of an eighth or a tenth.

So far as the bare land is concerned, no workman's house should be erected on land that in an unimproved condition costs more than an eighth or a tenth of the complete dwelling. One of the curious facts is that the provinces where land is most plentiful in relation to population are finding it most difficult to comply with this suggestion. In one of the old towns of Ontario, land is being obtained for building house at \$20 per lot, which will represent about one one-hundred-fiftieth of the completed building. The effect of this will be that the purchaser will be able to spend an extra \$200 on his house more than he could have done on land costing the ordinary price in a small town. This \$200 will go to supply those improved sanitary facilities that are usually left out through lack of means caused by too much money having been spent on the site.

Canadian Scheme Suitable for United States

I commend the Canadian scheme to the consideration of this Conference as an example that might very well be followed in the United States. That government should have its Federal office of housing and town planning, a coordinating and advisory bureau. The war has been won by organization as well as by the splendor of our men. If it had gone on a few months longer you would have wasted more than you now need to spend in solving your housing problem. The Federal Government should offer a sum of money, which to be equivalent to the Canadian appropriation, would be about \$300,000,000, to assist the states to carry out housing and town planning schemes. This money should be lent at 4 per cent to be equivalent to our 5 per cent. It should be lent to your state governments after consultation with them, and after settlement with them of the principles that would govern the spending of the money on housing schemes. Each state would prepare its own housing scheme, and one main condition of any Federal scheme should be that such a state scheme be prepared and approved before any loan is granted. Under state control the municipalities or housing commissions would work out the problem locally and would build houses where needed.

To make housing improvement more effective, however, it will be necessary to have better and more general town planning legislation in the states and to unite administration of housing and town planning together in a state department.

It seems difficult to believe that the American people with all their resourcefulness, their love of freedom and humanity, and their unequalled opportunities will let their program of reconstruction continue to have the defect that it does not

deal adequately with the most pressing social problem of our time. All of us realize what the housing problem is to-day in our big cities. In New York and Montreal it is getting beyond our control by any means within our power. Let us ask ourselves what the problem will be in twenty years hence when the slum population have multiplied more rapidly than other classes of population, and the slum areas have grown relatively

greater than now to our healthy areas, and the great cities are spread over double their present territory. There is hardly another social question to which it is more important that we should apply our energies, and there are few other social problems that can be effectively dealt with, without at the same time dealing with the problem of improving housing conditions.

TRAINING FOR MEDICAL SOCIAL WORK

A DESCRIPTION OF THE COURSE OFFERED IN THE TRAINING SCHOOL OF PSYCHIATRIC WORK AT SMITH COLLEGE,
NORTHAMPTON, MASS.

THE training of students for medical social work has been undertaken by Smith College. Last year the college offered a course of training for psychiatric social workers under the auspices of the National Committee of Mental Hygiene, in view of the anticipated demand for social workers in neuro-psychiatric wards of army hospitals. The increasing demand for trained social workers in several fields in which activities will be expanded during the reconstruction period led to the establishment of the Smith College Training School for Social Work. The fifty odd graduates of last year's course were immediately absorbed in positions in military and civilian hospitals and social agencies, and the need for trained psychiatric social workers is still acute.

The importance of increased facilities for training medical social workers was recognized at the last annual meeting of the American Hospital Association, when the following resolution, proposed by Dr. A. R. Warner of Cleveland, was passed:

Resolved: That the American Hospital Association express a recognition of a general need of a large number of women to supervise hospital social work, who shall have the advantages of training by a university in preparation for such work; that the essential elements in such education are (1) general education; (2) medical; (3) sociologie; and that this work be so combined as to make a university course of reasonable length.

And Be It Resolved: That the Executive Secretary shall send copies of this resolution to such universities as do now give practical courses in philanthropy and sociology and to any other universities contemplating the establishment of such courses.

Recently Dr. Richard C. Cabot of Boston, who is chairman of the Advisory Committee on Medical Social Work of the Smith College Training School, has issued the following statement:

"For three reasons the demand for medical social workers is increasing fast.

"(1) Hospital physicians who have worked with the Red Cross in France or in

this country have realized in the past two years that social work is an indispensable ally to good medical work. Disease can never be fought effectively on any large scale in hospitals, dispensaries, schools or factories without detailed hygiene education and without financial advice and aid. This is being brought home more clearly month by month to the community simply because war has brought us up against the facts.

"(2) The increased attention given to industrial disease and industrial welfare during the war is sure to be magnified still more by the fact that labor and all its interests will be more and more prominent in the public conscience during the next few years.

"(3) The problems raised by the wounded or mutilated from the United States service will call for the best team-work of doctor and social worker.

"In view of these facts, there is an urgent need for more and better social workers specializing in the medical field."

The new school at Smith College offers training courses in medical social work, psychiatric social work, community service, and an advanced course in child welfare which is open to persons already engaged in social work with children. The training courses are open to college graduates, or persons of equivalent education. Experienced social workers and teachers may be admitted to the summer sessions. The work of the training courses falls into three divisions, a summer session of eight weeks of theoretical instruction, combined with clinical observation, a training period of nine months practical instruction carried on in cooperation with hospitals and social agencies, and a concluding summer session of eight weeks of advanced study. The summer sessions are held at Smith College, Northampton, Mass. The practice work will be done in a num-

ber of centers—Boston, New York, Baltimore, and Philadelphia—under supervision of a local leader, with weekly group conferences.

According to this plan of concentrated study and practice, it is possible for the student to complete practically two years' work in thirteen months. The method of continuous practice is believed by many to afford the best practical training, as a student who gives full time to the work becomes completely assimilated into the organization in which she is engaged, and obtains richer experience when on duty regularly and without interruption. This method is an experiment which was tried successfully in the emergency course in psychiatric social work given by Smith College last year.

Student's Pathway of Approach

The school announces its special aims as follows: First, the psychological approach to social problems is emphasized in all of its courses; second, students are made acquainted with the applications of the scientific method in sciences bearing upon social problems—biology, psychology, sociology, psychiatry, and medicine; third, emphasis is laid on the discussion method of teaching rather than the use of the usual lecture system, in an endeavor to train for fearless and resourceful thinking about social problems; and fourth, the intense group life of the students in college dormitories and in continual association with their instructors permits a high degree of concentration.

Base courses in psychology, sociology, and principles of social case work will be required of all students. Those in training for medical social work will specialize in social medicine; those preparing for psychiatric social work will specialize in social psychiatry; those preparing for community service will specialize in social psychology and community organization. Each section will be under a group leader who is an experienced social worker in that particular field. The medical branches will be taught by experienced physicians with the assistance of visiting lecturers eminent in special fields of medicine and psychiatry.

From the standpoint of training for medical social work this experiment is unusually interesting. The trend in medicine for several years has been to force the physician to be an educator and a psychologist as well as a healer. Obviously he cannot be all this without help, and it is in these two newer aspects of his profession that the medical social worker can be of greatest assistance. Such a worker is concerned with the aspect of healing only in so far as she can assist

in securing tools for the doctor's plan. On the educative or preventive side of the doctor's work, however, she is almost essential. Treatment, to be truly effective, requires attention not only to the symptoms of the disease, but to the entire personality of the patient, and symptoms may be unduly prolonged because of the patient's mental worry over conditions which the doctor cannot control. In helping to bring about a subjective feeling of well-being in the patient, the social worker may have some part in the healing.

Her part, however, is never at any time a medical function: She is a social worker first and always, and her training should be essentially along social and psychological lines. She should know, as should all social workers, the structure and functions of the body and the important rules of health. In addition she should know enough of medical terminology to give her a working basis. She should know as much as she can absorb of the etiology of disease, something of prognosis, much of ethics, and above all she should understand the social aspect of disease both as it affects the individual and the community. As her work is primarily with the individual, she should know much of practical psychology. In brief, the medical social worker is essentially a social worker whose work is in the medical field.

RICKETS A FACTOR IN HIGH DEATH RATE AMONG TOWN DWELLERS

"The European range and frequency of rickets have long been realized, but it is doubtful if the indirect influences of this disease have met with adequate appreciation. Taking an average from a large number of examinations of children in towns and densely populated areas, it is found that over seventy-five per cent show some evidence of the condition. One of the greatest dangers constantly menacing the health of civilized communities, namely the future development of defective and carious teeth, has been shown to bear a very definite relation to the rachitic condition, and, if the results be followed further, it is seen that the markedly reduced resistance of the rachitic child may not only account to a large extent for the enormous loss of infant life in poor urban districts of this country, but also predispose in later youth to fatal terminations for normally subacute illness or to infection by organisms such as tubercle bacilli or low-grade streptococci, against which the healthy body has considerable powers of resistance. It is more than probable that, although not in itself a fatal disease, rickets may be one of the most potent factors in the relatively high death rate among all town dwellers."—*The Hospital*.

CLASS IN OCCUPATIONAL THERAPY

The opening of a class in occupational therapy for the training of teachers and instructors in that work, is announced by the St. Louis School of Occupational Therapy, in the first issue of a bulletin published by the school. The class will be opened about September 1. The course

is designed to prepare students to teach occupational therapy to physically and mentally handicapped persons, and convalescents in public and private hospitals. The school will try to supply reconstruction aides in government hospitals while the rehabilitation of disabled soldiers continues. An account of the work which is being done by St. Louis hospitals in vocational training and occupational therapy was contained in an article written by Professor G. Canby Robinson, of the Washington University School of Medicine, on "Occupational Therapy in Civilian Hospitals," which was published in the June issue of MODERN MEDICINE.

THE INFANTILE PARALYSIS PROBLEM

BY CLARENCE W. EAST, M.D., CHIEF, DIVISION OF CHILD HYGIENE, ILLINOIS STATE DEPARTMENT OF PUBLIC HEALTH, SPRINGFIELD, ILLINOIS

The Problem Stated

Acute poliomyelitis is endemic in the United States. The states of the North Atlantic Seaboard suffered repeated seasonal outbreaks from 1907 to 1916.

Illinois has probably passed through the third consecutive year of epidemic incidence of acute poliomyelitis, about 1,000 cases having been reported in 1916, a like number in 1917, and about 700 in 1918. The epidemic prognosis is grave for several years to come.

Other nearby states, as Minnesota, Wisconsin, and Iowa have suffered severe local epidemics. It is reasonable to assume a cyclic appearance of this disease in a group of states, especially about a greater center of population like New York City or Chicago, this cycle lasting over eight or ten years, when incidence drops again to the sporadic level.

Other sections of the country have had epidemic outbreaks on a smaller scale, which may take on a cyclic type and multiplied incidence.

In the absence of a generally acceptable or available specific or prophylactic treatment the facts just stated present a problem in the prevention of crippling, appealing to physicians, nurses, parents, and the public generally.

If considerable sections of the nation are to have several successive annual crops of cripples it behooves us to do what we can to meet the situation.

The convalescent stage of the first two years offers the opportunity for successful work.

The medical and nursing professions, parents, and the public generally must be taught the supreme value of rest, prevention of deformity, and retraining of muscles.

Services in afflicted centers must be established where patients may be examined and advised, and the medical and nursing professions taught the few simple principles which belong to the treatment of the convalescent stage.

A follow-up service is to be provided for the care of cases between clinics.

A fund in each locality is to be secured to buy braces and afford hospitalization for those in need of such aids.

A series of clinical centers should be established in connection with hospitals and social settlements. The members of the local nursing organizations are to be trained by clinical demonstration and exact prescription in the after care of each case.

Physicians are to be urged to retain charge of their patients as far as they desire.

County, township, and city officials, local philanthropists, and philanthropies should be interested in the financial requirements.

Each clinic is to be visited once in two weeks by a qualified physician in state employ. This physician should have associated with him at least one nurse who has learned or will learn the general principles of after care during the convalescent stage, and become skilled in muscle training, and also acquainted with the sociological side of the enterprise.

During the current year sixteen clinical centers have been established in Illinois. Four more centers have been visited from two to six times. Our detailed reports show the following facts in round numbers:

Patients seen at clinics.....	900
Revisits made to patients in houses.....	2,000
Number braces, casts, shoes, and appliances	600
Number receiving muscle training.....	400
Cases sent to hospital.....	37

We give six months' supervision of acute cases at intervals of two weeks. Then the interval is lengthened.

We find that other cities make application for clinical service and these requests are met as lengthened intervals in established clinics enable us to respond. One or more physicians in each center take an interest and attain competency to handle their own cases during the convalescent stage.

Members of nursing associations and students in training become informed and some of them become proficient in muscle training.

In some instances counties have provided a brace fund; in others, individuals and organizations have adequately contributed, so that no patient has had to go without a needed orthopedic appliance.

Old and severe orthopedic cases have been discovered and weeded out, and have been referred to surgeons for operative help.

Quacks and charlatans have been quite largely limited and discredited as far as the care of infantile paralysis is concerned.

An atmosphere of hope has been created which contrasts with the spirit of dismay which formerly swayed both professional and popular mind in the presence of epidemic poliomyelitis.

MUNICIPAL HEALTH WORK IN INDIA

The Madras Medical Journal, in the March issue, publishes an article by C. Singaraveloo Mudaliar, L.R.C.P.&S., assistant health officer of Madras City, dealing with the problems and faults of practical health measures employed by the municipality of Madras.

The state of sanitation in public places in India at the time of the British occupation, and the neglect of public health throughout the territory, corresponded to that of the Middle Ages in Europe.

The domestic life of families was such as to impede any effort in the direction of public health or control of municipal areas by the health authorities. The streets were narrow; the houses were crowded close together without regard for light and air; there was no provision made for disposal of waste and filth; and the drainage of cities scarcely deserved the name.

To make a bad situation worse, many of the residents dwelt in houses which closely adjoined the cattle sheds and sheep folds in the outskirts of the cities. Not until the nineteenth century were masonry drains constructed. For many decades the cesspools of the towns and cities were accumulating their disease-breeding residue until even the air was poisoned in their vicinity. The condition of the sub-soil in the city of Madras was deplorable it

was found when excavations were made in the 70's for the installation of water mains. The water supply was taken often from wells, tanks, and ponds in proximity to drainage ditches, sewage, and stagnant pools of water.

Chronic diseases, plagues, and epidemics exacted a large toll in deaths, and sickness prevailed in a considerable amount at nearly all times.

Since the year 1863, when Municipal Boards and municipal health departments were established, a steady advance has been made in the prevention of these diseases by removing the conditions that gave rise to sickness, plagues, and epidemics.

With the establishing of Municipal Boards it became possible to take the census of population in Madras and other municipalities. Next an endeavor was made to collect the vital statistics. An accurate registration of births has been accomplished by the employment of health visitors and corporation or municipal midwives. Deaths are reported with reasonable accuracy, but difficulty is encountered in obtaining full particulars for the purpose of amplifying the vital statistics.

Among the problems that have been dealt with quite successfully are ventilation, inferior foods, unhealthful dwellings, unclean streets and thoroughfares, sewage and garbage disposal, animals, plagues, malaria, vaccination, and relief of poverty. The author devotes several paragraphs to a discussion of the difficulties encountered and the methods taken to remedy each variety of neglect and insanitary practice.

"Interest in securing good roads need not be relegated solely to the engineer; in this matter the sanitarian should be a coadjutor," comments Dr. Mudaliar. He continues: "Public ways should be therefore, as far as practicable, so paved, metalled, or gravelled and tarred as not to favor inhibition or other retention of filth."

"The extension of gravelled or metalled streets into all *paracherries* and hutting grounds is essential for the cleanliness of soil and air, and it is the prime duty of a medical officer of health to see that roads are well made, kept in proper order, and watered regularly to allay the dust."

Of drainage systems, he writes: "Though the provision of effective drainage is an engineering task, the sanitarian should find out whether a system of drainage works badly or well, and suggest the character of engineering methods by which the defective drainage may be amended. He should see that the sewers are ventilated inoffensively by a perfect system of trapping."

Since the introduction and working of the drainage system installed in the three divisions of Tondiarpet, Madras, the death rate has fallen from 48.2 in 1911, to 44.6 in 1917. Similarly, measures for sanitation in the division of Nungumbakkam, Madra, effected a decline in the death rate from 72.9 per square mile for the period 1859-1861, to 22.8 per square mile in 1885. The chief corrective steps taken were the removal of accumulated filth, and the planting of trees, digging of ditches, opening of roads, the widening of streets, and the improvement of housing.

Supervision of food and the methods of handling, and control of the milk supplies, have been effective means for improvement of general health conditions.

Soldiers Return in Good Health

Uncle Sam gave a clean bill of health upon discharge to more than 93 per cent of the 2,000,000 officers and men of the United States army who have been demobilized since the signing of the Armistice. The Surgeon General

of the Army announces that up to July 9, six per cent of those discharged had been reported to the Bureau of War Risk Insurance for disabilities, and that one per cent were being held in service on account of communicable diseases or other causes.

LAW FOR THE DOCTOR

BY LESLIE CHILDS, ATTORNEY AT LAW, INDIANAPOLIS, INDIANA*

Are the services of a physician a valuable thing under a statute which prescribes a penalty for obtaining a "valuable thing" by false pretenses?

The above question was passed upon by the Supreme Court of Mississippi in the case of State vs. B. B. Ball, 114 Miss. 505. The case was unique because of the point of law involved. It was also interesting, and not entirely devoid of humor, because of the facts which were substantially as follows:

It appears that B. B. Ball was in the market for some medical services, and that he was not in a position financially to pay for them at the time. He therefore represented to Dr. J. B. Magee that he was the owner of one red cow about two years old, and agreed with the doctor, that in the event he (Ball) failed to pay for the services on or prior to a certain date that the doctor was to have the cow.

It further appears that the doctor rendered the services to the value of fifteen dollars, and that Ball failed to pay for same. We take it by implication that thereafter the doctor demanded the cow, and, no doubt much to his surprise, learned that Mr. Ball never owned such an animal, nor one that even remotely resembled the animal so vividly described by him when applying for the services.

This discovery of the perfidy of Ball appears to have aroused the doctor's righteous indignation. In any event, the following affidavit was filed against Ball under a penal statute providing for the punishment of those who obtain "any money, personal property, or valuable thing," by false pretenses. . . . Then and there knowingly, . . . and with the unlawful intent and purpose to cheat and defraud one J. B. Magee, a medical doctor, represent, pretend, and claim to the said Magee that he, the said Ball, was the owner of a certain red cow about two years old, and that for medical attention rendered or to be rendered the said cow should become the property of the said Magee, unless the said Ball should pay said Magee the sum of fifteen dollars for said services . . . when in truth and in fact the said Ball at said time did not and knew that he did not own the said animal or any other animal of a like description.

"And by reason of the said false representation, . . . did then and thereby procure . . . medical attention to the value of fifteen dollars, which he otherwise would not have received, . . . and against the peace and dignity of the state of Mississippi."

Ball was tried and convicted in the justice court, from which he appealed to the circuit court. The latter court decided in his favor by sustaining a demurrer to the affidavit for want of sufficient facts. In other words the circuit court held that the services of a physician were not "a valuable thing," or subject to be obtained by false pretenses, under the statute in question.

The state appealed from the ruling of the circuit court and the Supreme Court in passing upon the point raised said: "The exact question raised in this case is whether

*The fourth of a series of articles on "Law for the Doctor," written for MODERN MEDICINE by Leslie Childs.

or not the professional services of a medical doctor is 'personal property, or valuable thing,' or, to present the point more sharply, are the services of a physician 'a valuable thing'?

" . . . We think the object of the statute is primarily to reach the mischief of fraud or deceit practised by one person upon another in obtaining something of value by such deceit or false pretenses. . . . In the case before us the thing obtained by the false pretense and deceit was the services of a physician of the value or worth of fifteen dollars. . . .

"The services of the wage hand in the field or the employee in the factory or the professional services of the lawyer or doctor are valuable. . . . Therefore the services of the physician in this case is a 'valuable thing,' and when obtained by false pretenses and deceit the statute has been violated, and the guilty person is liable to prosecution thereunder. . . . This case is unusual in its facts, and is rather of minor importance so far as this particular case is concerned, and we hope that the old red cow will show up before another trial is had in the lower court, but we feel certain that the conclusion we have reached as to the principle of law involved is correct and sound."

The judgment of the circuit court was thereupon reversed and the case remanded.

NORMALIZING THE INDUSTRIAL CRIPPLE

By ELIZABETH G. UPHAM

(Reprinted from *The Vocational Summary*)

Study of the mental and emotional states of the returned man disabled in the war has shed an illuminating light upon the psychology of the handicapped. Failure to recognize the importance of the psychic factor in the case of the war disabled spelled failure in the effort to reeducate him. Normalizing the soldier's attitude has been the first essential in rehabilitation work, and from this point on has proceeded vocational training and preparation for placement in industry. It is equally necessary to understand the mental and emotional reactions and conditions of the victim of industry if the effort to rehabilitate him is to succeed.

It is to be noted, however, that the victim of industry has a definite point of view which differs from that of the victims of war, just as really as the circumstances and environments of military life differ from those of civilian life. This contrast in the reactions of the returned man and the civilian patient is further intensified by the future awaiting them and the attitude of the public that must absorb them.

The victim of industry comes directly from civil life. Whatever traits, such as ambition, initiative, skill, perseverance, carelessness, or shiftlessness, he may have possessed before his disability, they will tend to persist after his disability. He, unlike the soldier, has not been through months of military training or life at the front, where individual ideas gradually give way to blind obedience to orders. He is accustomed to depend upon himself. He therefore needs no gradual readjustment to civilian life; and in this respect his problem is less complicated than is that of the war disabled.

On the other hand, the handicapped soldier has advantages which the victim of industry can not have. However disabled the soldier may be, he knows there are hundreds of his comrades sharing the same experience. To be one of them, and to carry on with his fellows, is a real incentive. Furthermore the soldier is conscious that

his disability was incurred in a heroic cause, a cause that places him on a pedestal. This mental satisfaction actually assists his recovery. Professor Amar, the notable French specialist, has observed that soldiers who have performed some praiseworthy act and are consequently happy, recover rapidly. But the greatest advantage which the disabled soldier possesses over the man disabled in industry is the attitude of a grateful public. The man disabled in industry lacks the stimulus of community activity. He is not one of many, but alone and unknown he must pass through the tortuous experience of disablement. He has not the gratification of having incurred his handicap in a great cause. He was merely one of the vast throng of toilers. He has just simply dropped out. No public awaits him with outstretched hand, eager to show appreciation for his service. Rather he knows that his disability will increase the difficulty of finding employment, and that his handicap, instead of being a mark of service and distinction, will tend to make him a social as well as an economic outcast.

If the disabled soldier needs encouragement to prevent the despair of facing life with a permanent handicap, so much more does the man disabled in industry need such encouragement, facing his misfortune alone, as he does, and unaided by the sympathy of the public. It is the hopelessness of the outlook of the disabled civilian which is the root of the well-known "psychology of the handicapped." The reaction to a hopeless outlook may be to accept it with apathy and indifference, or it may be to assume the defensive and blame society and the disability for laziness and lack of effort; or again it may be to struggle against odds with superhuman endeavor until discouragement has completely broken the spirit.

If the man disabled in industry is given the same opportunity as the man disabled in war, if his peculiar attitude of mind is understood, if he is prepared for the circumstances he must meet in industry, and if his way is led by an intelligent public, the handicapped man may become a national asset of which his country may well be proud. He will be a credit to himself and his community. It has been said that this country shall have cause for national pride if the man disabled in war shall date his prosperity from the time of the disability incurred in his country's service. How much greater the cause for national glory if the vast throng of toilers who country are reabsorbed into the national life in such a way that they may realize self-respecting, independent, are every day disabled in the economic struggle of their useful, and happy lives.

REHABILITATION OF TUBERCULOSIS

Dr. H. A. Pattison of the National Tuberculosis Association has written a descriptive and statistical account of his investigations into the problems of community life and environment which are encountered by tuberculosis patients when returning from a sanatorium or hospital to their homes. His studies have dealt with the colonies of consumptives in sanatoriums, in respect to extending the idea of the colony to communities in which would reside persons who had left the institutions, but who still desired to protect themselves and others by following the practices of the sanatorium, while going about their business of family affairs.

The Federal Board for Vocational Education publishes the paper in Bulletin No. 32, Reeducation Series No. 6, under the title, "The Agricultural and Industrial Community for Arrested Cases of Tuberculosis and Their Families."

THE FREE PUBLIC HOSPITAL MOVEMENT IN PROVINCES OF CANADA*

A very strong movement for free public hospitals, especially for the rural districts, has been sweeping the West. There has been an increasing demand that provincial governments assume a greater measure of responsibility for public health. This has, no doubt, been brought about by what has been accomplished by the military medical departments. It is urged that if a complete medical and hospital service can so improve conditions among soldiers, an equally complete service for civilians would have the same result.

Each of the prairie provinces, in response to this agitation, has enacted legislation. Saskatchewan and Alberta have passed hospital acts providing for public hospitals to be controlled and financed by the taxpayers of the districts which they serve. The Alberta act is considered the most advanced measure enacted anywhere in Canada. It recognizes more fully than the Saskatchewan act the primary responsibility of the government, and provides a scheme of organization closely paralleling that for education, in which the government assumes the initiative in all organizations. The Alberta act lays the foundation for a system of hospitals as complete and gratuitous as the public schools. It is based on the principle of the direct responsibility of the state for maintaining the health of each and every citizen. The office of minister of municipal affairs is combined with health matters. Alberta has paved the way for a revolution of the present methods of safeguarding health; it provides the minister of health with adequate machinery to carry out a progressive democratic policy for complete nationalization of health within the boundaries of the province.

The act provides for alternate initiative by the minister and the ratepayers. This prevents action by the government before the ratepayers of a given district are ready for action, but gives the minister full general supervision over the administration by the local boards of each district. The minister establishes the districts; the ratepayers, by petition, set the machinery of the act in motion, the district board then assumes the executive, establishing a hospital having the benefits of provincial architects, medical staff to advise them as to plans, costs, etc., and the scheme is submitted to the ratepayers. Individual ratepayers have access to the Board of Public Utility Commissioners for redress for a wronged minority. These commissioners also adjudicate on disputes as to site when the various sections of the district fail to agree. Formerly many municipalities had endeavoured to combine by mutual agreement to form hospital districts, but, with the exception of Lloydminster, the plan failed owing to dispute over sites, the inertia of one municipal council or the hostility of another. By the present act it is believed Alberta will be much better served, as many local improvement districts would have been left isolated owing to financial inability to participate in the organization of the district to which it naturally belonged. The Alberta act differs from the Saskatchewan act in that the latter does not provide for such extensive government initiative.

Promote Study of Mental Diseases

The creation of a national institute for study and research of mental diseases is advocated by Dr. Harvey Cushing, who was in charge of brain surgery in the American Expeditionary Forces. He set forth the idea

before the convention of the American Medico-Psychological Association at Philadelphia, in June. He also urged close cooperation between the three branches of neurology — neurologics¹, surgery, psychology, and psychiatry.

AN AMBULATORY CHAIR

BY FRANK G. NIFONG, M.D., F.A.C.S., COLUMBIA, MO.

It is our duty as physicians and surgeons more fully to recognize our obligations to our convalescent patients recovering from both injuries and illness and to see that they reach complete mental and physical restoration. This

Fig. 1. Illustrates the ambulatory chair and the patient entering the chair from the bed. It must be made of light, strong wood. It must not be too wide but freely pass through the average 2 ft. 8 in. of door. Length at bottom, 47 in.; width at bottom, 29 in.; length at top, 49 in.; width at top, 24 in.; height of seat, 16 in.

accords with our newer ideas of the duties of the state to those who have served us. We should each realize more fully this obligation to our individual patients and stay with them during what is often a most difficult and trying experience and help them to "carry on" to complete recovery. No device, suggestive, mechanical, or what-not, which may be helpful should be overlooked. Mental suggestion and all manner of encouragement are necessary to promote the more rapid restoration of the fever patient during his convalescence, and this should not be left to the unskilled. Those fractures and injuries of the lower extremities which necessarily have been treated in bed for a long time often leave the patient in a most deplorable state, which requires all the skill and patience of physicians and attendants if successful recovery is attained. After such injuries and protracted illnesses it is not only the emaciation and flabby muscles with which we must deal, but a mental state equally flaccid which must be overcome.

It is a proper estimate of the real condition of such a patient which we wish to emphasize and we desire to protest against the perfunctory prescription of a pair of crutches and such unskilled help in getting up and out as may by chance be available.

This weakened mental and physical state so analogous to that of a little child beginning to walk, has suggested the helpful appliance which I wish to present. It is simply a modification of the well known baby-walker adapted to the needs of such patients.

*From the Canadian Medical Association Journal.

Figure 1 fairly represents the device. It should be made of light, strong material preferably of hickory or ash, and of dimensions which allow passage through ordinary doors. The end opposite the seat should be open, as shown, so entrance from the bed may be easy.

The manner of walking and supporting the weight of the body partly by the arms is shown in Figure 2. At any moment, when the patient feels faint or tired, he may sit down, as shown in Figure 3. With four points of support in addition to his own legs the patient is very soon able to walk and even ascend and descend stairways with perfect safety.

Some very good reasons for the use of this chair and its adoption as a part of the armamentarium of well regulated hospitals might be given.

In the first place, it inspires confidence in the convalescent and cripple and quickly promotes self-reliance, which is such a necessary factor in hastening recovery. He soon goes alone and much more quickly than if he depended on attendants. He realizes that he is supported by a broad base and has no fear that he may fall. He sits down as soon as he is tired. He enters from his bed with ease and may be encouraged to take care of himself from the beginning of his efforts, which is so important psychologically.

In the second place, the patient needs much less assistance from attendants and very soon may do without them. This is not an unimportant consideration when convalescence may be a matter of weeks and months.

In the third place, there is no danger from disastrous falls, from pressure paralysis and consequent wrist drop so often seen in weak and emaciated patients who have tried to use crutches. It is well known how much delay in recovery is experienced when such an accident supervenes.

In presenting this rather simple device it is hoped to emphasize that the full duty of the physician to such patients is not discharged by prescribing crutches and leav-

Fig. 3 Sitting in an ambulatory chair.

ing them to their own fate, but that the obligation extends further and is not finished until the patient is helped to ultimate functional recovery.

SEEK MORE COMPLETE REPORTS ON COMMUNICABLE DISEASES

To secure the enforcement of state laws under which physicians are required to report cases of communicable diseases, and to better guarantee the active support of all members of the medical profession, a resolution was approved at the American Medical Association by the section which declares its attitude on the question in the following words:

"Resolved, That the Section on Preventive Medicine and Public Health of the American Medical Association recommend to the House of Delegates that it ask the constituent associations to consider the advisability of such amendments to their by-laws and to those of this Association as will eliminate from membership any physician who willfully fails or refuses to comply with local or state laws for the prevention of disease, including especially the provisions in such laws requiring the reporting of cases of communicable disease."

"The enforcement of such an amendment to the by-laws as here proposed," declares a writer in *Public Health Reports*, "would be of incalculable value to the public health movement. It would make it possible to bring delinquent physicians before a court consisting entirely of their peers. This would make the American Medical Association insist that membership in the Association depend on the faithful performance of the physician's duties not only to his patients, but to the public at large."

"Emerging from a period of war in which billions were spent for the destruction of human life, the saving of human life is the pre-eminent problem in restoring strength to a convalescent world."—Columbus (O.) Citizen.

THE MONTH IN MEDICINE

Survey of Current Medical Literature with Editorial Comment

WALTER W. HAMBURGER, M. D., Editor

REHABILITATION OF THE DISABLED HEART

IN THE Proceedings of the New York Conference on Hospital Social Service for 1912 Mrs. William K. Draper presented a committee report on "The Value of Industrial Training for Chronic Cardiac Cases," in which report she divides "cardiacs" in three groups:

(1) Cardiacs who can continue to be breadwinners; many even resume their former occupations.

(2) Another large class as well able to continue to be breadwinners as the former, but wholly unable to resume their former occupation. They should be wisely directed and given an opportunity to learn the trade it is thought they can work at without injury to themselves.

(3) A third class, whose cardiac power has been more nearly exhausted; though they cannot do continuous or hard work, through some form of light occupation they might still be partially self-supporting. For these cases an employment bureau could be of more service.

In conclusion, the Committee recommended the establishment of a training school for certain cardiac cases such a training school to have in connection with it an employment bureau.

The following year, Dr. N. Gilbert Seymour presented a committee report "On the Convalescent Care of Chronic Cardiac Cases." This Committee divides the problem into three component parts:

(1) The providing for a suitable convalescent home, to provide bed, rest, and care for the prolonged convalescence of an acute heart attack and to provide opportunities in which to study the patient, not only his physical capacity for work, but his mental make-up and limitations, so that an occupation might be selected for him which would really be suitable, both to his heart and to his mind; and that during the latter part of his convalescent period the patient might be trained in the occupation so selected.

(2) The question of industries suitable for these cardiac cases, and to report upon those deemed practical, with the estimated cost of teaching and equipment.

(3) How and where to employ cardiac patients, once taught, when their period of convalescence and industrial probation is done. Also, how to market the products of their work.

As a result of this report, a convalescent cardiac home was selected at Sharon, Conn., and was opened in July, 1913, as well as the Trade School for Cardiac Convalescents. At Sharon the patients were to be resident at the home for several months during which time they were under treatment and learning the trade of cement flower pot making.

In 1915 Dr. Seymour presented a final report on the "Sharon Cardiac Experiment." Summarizing the work is the following conclusion:

(1) Protracted convalescent care under select medical supervision is essential. The duration should be determined by individual improvement. The average will be between four and five months.

(2) Industrial training during convalescence has a therapeutic as well as an economic value. There was a marked contrast between the progress of the early patients before the industrial work was established and that of the late ones who have had the benefit of the work as occupation.

(3) As long as the number of patients must be limited, they should be selected from the group most in need of this special care, *i. e.*, adult males with moderately severe heart disease and laborious occupations.

(4) We may claim to have demonstrated two of our three propositions. We can now confidently state that chronic cardiac cases can be taught a suitable trade and can keep well while they pursue it in a suitable environment and under proper restrictions. We have yet to demonstrate that they can be made wholly self supporting in such employment, and we have not yet discovered more than one suitable industry.

Meanwhile, what was two years ago a problem of medical social science has now become, through the operation of the Workmen's Compensation Act in this state, a civic problem of tremendous significance. We recognize the fact that our constitution, whatever its value, can solve but a fraction of the great cardiac problem which is second only to tuberculosis in its magnitude.

In the discussion which followed Dr. Seymour's report, Dr. Guile described the work of the Cardiac Clinic at Bellevue Hospital with the co-operation of the Social Service Bureau for the purpose of determining just what could be accomplished by the medical and social after-care of discharged cardiac cases.

This clinic is held once a week on Friday evening, the case is carefully studied both from the social service and the medical aspects in an endeavor to determine where the man's life has been at fault in the past. Almost invariably the occupation is found entirely unsuited to the physical requirements of the individual, and it is on the solution of this highly important problem that the success of this entire enterprise depends.

It is not difficult to determine what the patient can do, but it is a very different matter to find work that the individual can do without harm to himself. It is for that reason there is the need of a social service worker who is able to make an intensive study of this phase of the problem. Not infrequently it is found that upon investigation that an occupation which at first seemed ideal in truth proved to be most injurious. Again, it has been possible to make slight changes in a patient's work without necessitating his seeking other employment. The social worker has often found a desire on the part of the employer to cooperate.

"A few of the various duties of the social worker consist in investigating the home conditions of its patients, the number of stairs to be climbed, the amount of work done at home, how it can be made less. She follows up cases to see that patients attend the clinic regularly, and that the physician's orders are carried out.

"Many cases that have been on the verge of a break in their compensation have been tided over this crisis safely by a timely rest at home in bed. Other cases, since a change in occupation has been made, have had practically no symptoms referable to their hearts, and have become active wage earners once more."

"We have subdivided our cardiac cases into three groups:

"(1) Slight valvular defects, where reserve strength is scarcely impaired.

"(2) Serious cases who may or may not have

had one or more serious breaks in compensation.

"(3) Hopeless cases with practically no reserve strength."

Dr. Guile concluded that the plan as outlined in the Bellevue Cardiac Clinic would probably be the better for the vast majority of cardiacs; he considered the Sharon Trade School plan too expensive, and of limited use as it is able to care for only a small percentage of those requiring help.

Dr. Alexander Lambert coincided with the views of Dr. Guile; he spoke of the desirability of the establishment of a number of similar cardiac clinics to keep these patients in "cardiac equilibrium" and to this end he regards the social service worker as important as the physician.

Dr. Brush, superintendent of the Burke Convalescent Home at White Plains, which superseded the Sharon Cardiac Home, agreed with Doctors Lambert and Guile, and emphasized the value of special cardiac clinics and cardiac social service.

"Thus the larger, surer success for the cardiac society," he said, "seems to appear ahead in the dispensaries and social service departments of the cities."

As a result of these earlier studies in cardiac convalescence the development of cardiac classes, cardiac clinics, cardiac social service, etc., has grown apace. The Association for the Prevention and Relief of Heart Disease, organized and incorporated in New York in 1916, gives needed recognition in concrete form of the magnitude of the heart disease problem. The increasing medical, economic, and social bearings of this great question are coming to be recognized as of first importance.*

Kahn,[†] in a report and analysis of the female medical clinic at the Mount Sinai Hospital Dispensary in 1916, advocated a special clinic for cardiac cases in order to introduce educational and supervisory methods in phases of cardiac therapeutics, particularly for the early and milder cases of heart disease.

Peter Bent Brigham Hospital,[‡] Boston, started a cardiac class in July, 1915, "for the purpose of giving more individual attention to cases of cardiac disease than was otherwise possible." In the 1917 report of this hospital is found this statement in the discussion of the cardiac class: "We feel more and more convinced that in spite of the satisfaction it gives to do for older people, that those patients between twelve and forty years, with the emphasis of those under twenty, are the ones who will best repay our efforts."

*The Modern Hospital, October, 1916, vii, No. 4, p. 357.

[†]New York Med. Jour., 1916, No. 18, p. 1,000.

[‡]Peter Bent Brigham Hospital, Boston, 1911, Second Annual Report.

Miss Frances S. Thomas* has published an interesting resumé of the work of the Bellevue Evening Clinic for Cardiacs. The outlines the social phase of such work in the following terms:

"The home investigation of cardiac cases which follows the patient's first visit to the clinic brings out much,—unnecessary distance of home from work, prohibitive stair climbing, unhealthy or noisy surroundings, lack of recreation, over-crowding, under-nourishment, domestic worries, etc. Special care is given to vocational guidance and industrial adjustments. We make an effort to provide educational training for promising boys and girls between the ages of thirteen and twenty-four years of age. There are others who are able to fit into ordinary occupations if they are given vocational training. For the women there are dress making, designing, millinery, manicuring, lamp-shade making. For the men, in addition to basketry and pottery and other handicraft work, are also suitable jewelry making and repairing, toy making, and weaving. We believe patients between the ages of twenty-two and thirty may be placed in positions as watchmen, switchboard operators, doormen, elevator runners, etc."

Cardiac clinics are also being established in the West Barnes Hospital, St. Louis, Central Free, and Michael Reese Dispensary, Chicago, and one is contemplated at Cook County Hospital. The theory and practicability of these clinics have been demonstrated. All that is now necessary is to see them in operation and thus salvage many of these disabled heart patients. The return whether in the conservation of happiness, economic efficiency, industrial productivity, or self support for the individual and the family, may confidently be expected to be very large.

The following may be taken as an illustrative case; although extreme, it is nevertheless typical.

A. Z., man, age 64 years. He gave a history of acute rheumatic arthritis at the age of 22 years. The first cardiac trouble noted began with decompensation in June, 1916, when he came to the hospital for the first time. In the three years since he has returned eighteen times with cardiac decompensation, the average duration of each period in the hospital being three weeks. His occupation is that of putting lumber into a planer. He is compelled to stand all day at his work, often having to lift pieces of lumber weighing from 150 to 200 pounds. He is able to work two or three days and is then compelled to rest two or three days.

His hospital record is appended for the purpose of showing the needless waste of human material if rational management of the work and habits of such cases is not provided for. The expense of hospital and medical service, and loss of time,

when proper hygienic measures cannot be applied, in the aggregate far exceed the cost of adequate care.

HOSPITAL RECORD OF A. Z.—CARDIAC DECOMPOSITION

Date of entrance	Date of discharge	Duration of hospitalization (days)	Length of time outside hospital (weeks)	
			6 entrances	Average duration

WAR NUMBER OF AMERICAN MEDICINE

The June issue of *American Medicine* is a special war number featuring an article by Merritte W. Ireland, M.D., Surgeon General of the Army, on "Activities of the Medical Department of the United States Army During the War."

Salutations to the members of the medical profession who served their country in the war, at the front and in the United States, are presented by Secretary of War Newton D. Baker, Secretary of the Navy Josephus Daniels, General Pershing, Surgeon General Ireland, Surgeon General William C. Braisted, William C. Gorgas, Surgeon General, retired; Major General Leonard Wood, M.D.; Colonel Franklin Martin, M.D., Medical Corps, chairman of the committee on medicine and sanitation of the Advisory Commission, and chairman of the general medical board of the Council of National Defense; Lieutenant-Colonel W. J. Monaghan, M.D., Medical Corps; and Theodore Roosevelt, Lieutenant Colonel, retired, U.S.A.

An account of "Medical Activities of the United States Navy Under Admiral Sims' Command" written by Henry Reuterdahl, Lieutenant Commander, U.S.N.R.F., appears in the June issue.

American Public Health Association

The dates for the forthcoming session of the American Public Health Association, at New Orleans, will be October 27 to 30. The meeting will take place at the Grunewald Hotel. Information will be supplied upon request to the executive secretary, A. W. Hedrick, 169 Massachusetts Avenue, Boston, Mass. The president of the Association is Lee K. Frankel, vice-president of the Metropolitan Life Insurance Company of New York.

American Society of Tropical Medicine

Officers were elected at the meeting of the American Society of Tropical Medicine at Atlantic City, during June include Henry J. Nichols, Lieutenant Colonel, Medical Corps, United States Army, president, Washington, D. C.; Dr. John M. Swan, vice-president, Rochester, N. Y.; Dr. Carl F. Meyer, vice-president, San Francisco, Cal.; Dr. Sidney K. Simon, secretary and treasurer, New Orleans, La.; Dr. Allen J. Smith, assistant secretary, Philadelphia, Pa. New Orleans was selected as the location of the next annual meeting, which will be held in connection with the meeting of the American Medical Association in 1920.

COLLECTIVE ABSTRACT—THE CAUSATION OF CANCER—OLD AND NEW THEORIES

BY J. RAWSON PENNINGTON, M.D., F.A.C.S., CHICAGO*

IT is not the intention to consider in this paper all the causes which have been invoked to explain the origin of malignant disease, but merely to glance at a few—especially several by laymen. It would be a striking example of poetic justice if one of them were fortunate enough to light on the cause, as did Schaudinn for that of syphilis.

Ehrlich once stated that the cancer problem will be taken by assault, but Gaylord¹ in his address before this very society, expressed the belief that it will be broken up into a great field, requiring many years of patient work of many investigators. This was barely four years ago, and "many years of patient work by many investigators" had already been done, though it is rather discouraging to think that we are not much nearer the cause than in the days of humoral pathology. Indeed, Ewing² doubts whether we shall ever have more than a descriptive knowledge of the ultimate nature of neoplastic overgrowth.

Parasitic Origin of Cancer

We may begin with the parasitic theory which is by no means new; for as long ago as 1801, Adams, of England, attributed malignant disease to what he dubbed "carcinomatous hydatid." Andrewes³ points out an insuperable objection to this theory. These growths are of limited inocuability. This would seem logically to involve for each species liable to cancer a private and particular variety of parasite incapable of producing cancer in any other sort of animal. "Such a view is incredible in face of the close resemblance between the growths in different vertebrates."

Both vegetable and animal parasites have been incriminated. Welsh⁴ remarks: "The resemblance between the invasion of a cancer and other infective processes which have been compelled to yield the secret of their origin fostered the expectation that the cause of cancer also would be found in some form of microbe." The enthusiasm excited by the discovery of the tubercle bacillus led to search for microbes in tumors also, and one of the most noted microbial causes in its day was Scheuerlen's⁵ bacillus which proved to be a common variety, growing freely on sliced potato. The latest claimant was the *Microcoecus neo-*

formans of the late E. Doyen, of Paris, which, with its serum, is now solely of historic interest.

Several of the protozoa—those lowly organisms on the borderline between the vegetable and animal kingdoms—have been held responsible as well. So far back as 1891, bodies resembling microsporidia, one of the sub-classes of protozoa, were found in tumors and were likened by Pfeiffer,⁶ the authority on the protozoa, to plasmodiophora brassica—belonging to the subclass and living in the roots of cabbages, beets, etc. Somewhat recently (1905) Robertson and Wade,⁷ in England, claimed to have discovered this same organism in cancer and to have been able to grow it from fresh carcinomatous tissue.

The "golden-yellow organisms" of Schuller,⁸ turned out to be cork-cells from the material used in mounting the specimens. This explains why he discovered them in sarcomas, likewise in carcinomas. Though Myxosporidia, another subclass, are supposed to be found only in cold-blooded animals, the late Professor Jaboulay,⁹ of Lyons, was confident at one time that they were the cause of tumors, cancerous and otherwise.

There is no need of enumerating all the alleged parasites, but some mention must be made of transmissible tumors which afford considerable evidence in support of this hypothesis.

In 1911, Rous¹⁰ announced the finding in the domestic fowl of a sarcoma transmissible by the filtrate. The original tumor was markedly malignant as proved by its structure and by producing extensive metastases. The filtrate made cell-free by passage through a filter produced similar tumors by inoculation, though they increased much more slowly than by direct implantation. It also gave rise to metastases. Rous suggested transmission is either by (1) some minute parasite or (2) chemical stimulus. Since then he has found others, all sarcomata.

At one time it was debated whether such transmissible or transplantable tumors were true neoplasms or not, but Ewing² decides they are malignant tumors with certain peculiarities impressed

on them by the species. They have been observed in the mouse, rat, hare, dog, and chicken; and Jones¹¹ has recently added the guinea-pig.

We pass on to a consideration of "cancer-areas" and "cancer-houses," both urged in support of the parasitic theory, the argument being, of course, that the causal organism is resident in such areas and dwelling places.

Haviland,¹² in 1875, plotting the cancer deaths of females in England and Wales, concluded that in these countries, the highest mortality is found along the lower courses of rivers flowing through lowlying valleys and which overflow at high water. He elaborated on this a few years later and instanced the Thames valley as a marked example. His original essay was promptly challenged by Hirsch,¹³ who in his celebrated work stated it could not hold good generally; in Norway, for example, cancer is found principally at considerable elevations and in the mountainous districts.

Leamington, in the county of Warwick, England, is on a small stream which empties into the river Stour. Mason,¹⁴ after investigating 400 cases there, thought the ultimate cause will prove to be a germ, the habitat of which is a subsoil contaminated by sewage, and that it gains access through one of the mucous orifices of the body.

Urquhart,¹⁵ several years ago, corroborated Haviland's conclusion as to the Thames valley; all the districts immediately bordering on the river show a rate above the average for the whole of England. As the high rate is uniform on both banks, it suggests there may be a connection between the floods in the river and the cancer incidence, though exactly what, is not easy of explanation. Presuming cancer to be of parasitic origin, the drying vegetation left on the banks after floods may form a favorable soil for growth of the parasite.

Some further evidence on this point comes from far off New Zealand. While the mortality in general is the lowest in the world, the percentage of cancer deaths increased from 64 per 100,000 living in 1898, to 73 in 1907, according to Hislop and Fenwick.¹⁶ The former had occasion to treat 31 cases, some 6 of whom lived in the same house though not blood relations. The area was a flat district lying between a snow-fed river and a small stream, a large proportion being flooded every season.

Gordon and Thompson¹⁷ have recently furnished some negative evidence. Of the adjoining districts of Camelford and Launceston, in the Duchy of Cornwall, the first has one of the lowest death rates in all England, and Launceston one of the highest in the southwest part of that coun-

try. They plotted all deaths during a ten-year period. Since it has been claimed that cancer is relatively common in low clay levels along rivers which flood their banks, relatively uncommon on limestone, prone to occur among trees, and to recur in the same house, all these points were investigated. They found no special tendency to follow rivers except as the houses follow them; nor any influence from the underlying rocks. Neither did they find any particular prevalence in wooded districts or single houses. On the other hand, they observed a marked tendency to "pockets" of cancer districts, though it is uncertain whether these are due to chance or not.

Bertillon¹⁸ also described an enormous "cancer-area" which is referred to later on.

America is not to be outdone and is able to report "cancer-areas," as might be predicted in the older settled portions of the country, where the conditions of living approximate those of Europe. An example is narrated by Tynes,¹⁹ from Fisherville, Pa. His practice averages about 265 families, and there were in 9 years 105 deaths. Eighteen, or 17 per cent, were from cancer. Brooklyn, possibly the most celebrated "cancer-area" in the United States, with a population of two and one-half times as much as Fisherville, had but 9.7 per cent of deaths, nearly 9 per cent less than in Fisherville. Neither heredity nor consanguinity was an important factor.

Tynes gives further details of what he regards as the strongest evidence of the infectious character of cancer. In a city nearby, within six years there were 10 deaths from malignant disease in a sharply defined area not much larger than a city block. In fact, 5 cases not only occurred in the same street and the same block, but in five adjacent houses, and the rest close by. Case 1, making 11 deaths in all, developed cancer fifteen years before any of the others. She lived at the highest spot in the vicinity, and the drainage from her house was directly down grade and into five other houses in which cancer developed later. Only three persons were related, and they were sisters and a son. Here, also, a history of heredity was lacking.

So much for "cancer-areas." As for "cancer-houses," while the occurrences about to be mentioned are probably fortuitous, they are striking, nevertheless. In a hamlet in Shropshire, Eng-

land, with twenty cottages, 9 cases of cancer occurred in 15 years, according to Webb.²⁰ Though none of the patients were blood relations, all villagers used water from a roadside pump.

Power²¹ relates 3 deaths of domestics in the same dwelling: Miss B., aged 45, had lived in the house for thirteen years and died from gastric carcinoma in 1884. Miss T., who had lived there for twenty years, at the age of 47 succeeded to the position held by Miss B., and occupied the same bedroom. She died the following year from cancer of the liver. Miss J., who had also resided in the same dwelling for twenty-eight years, followed Misses B. and T., in the same bedroom, and succumbed to malignant growths in the breast and uterus in 1893. None of these women were related, and all appeared to be perfectly healthy when assuming the position.

During the discussion of Gordon and Thompson's paper, Ackerly²² said in Ashburton, in the southern part of Devon, he found an undue prevalence of cancer in the houses along a certain stream, in one, three successive occupants, not blood relations, developed carcinoma. In Surbiton, in the county of Surrey, he knew of four instances where, in the previous thirteen years some eight or nine individuals, long resident in the houses, succumbed to cancer. He suggested investigating the rats in such houses.

Another typical "cancer-house," and this time from Wales, is related by Simons.²³ It is old, and so large it had sometime before been divided by a wall. Under this roof there were 5 deaths in twenty-one years, and but 2 were blood relations. This house is on the side of a stream which, though often swollen by floods, is not sluggish, but the subsoil is often saturated.

An ingenious suggestion is made by Lazarus-Barlow,²⁴ namely, that the greater frequency of cancer in certain houses or districts may be accounted for by the presence of some radioactive substance in the soil itself or the material of which houses are built.

The explanation offered by Rosenfeld²⁵ for "cancer-houses" is that they are in poor repair, hence patients, on account of their poverty, dwell in them; but not all such houses are dilapidated, for Chapman²⁶ saw three cases in a fine mansion standing in large grounds; while Fabre²⁷ quotes a case from Molière: "In a well built house at Lyons on the banks of the river Saone, there were four deaths from cancer in ten years, and none from any other cause."

We come now to a much debated cause for malignant growths as well as many other conditions—heredity.

Probably the most marked instance of this alleged factor is the family alluded to by Broca.²⁸ This, it will be remembered, concerned a mother and four daughters, all of whom died of cancer; and of eighteen grandchildren, eleven succumbed to cancer. Whiteford,²⁹ recording a case of "conjugal cancer," furnished another striking instance of family incidence: the wife's father, two brothers, three aunts, and two cousins, all died from cancer.

In 1890, Arnaudet³⁰ claimed that cancer is much more frequent in Normandy than in Paris. A committee was formed, and after due investigation reported that while cancer was unduly prevalent in some remote villages, and which they believed due to inbreeding and heredity, still in Normandy as a whole, it is no more frequent than elsewhere in France. This point is referred to later by Bertillon.

During eighteen years, Warthin³¹ examined some 1,600 carcinomas, proved such by histological examination. Complete records of four families were available, and the incidence in them is so striking that, according to him, it can be interpreted as showing an inherited susceptibility. He believes also there is a marked susceptibility in certain generations and family groups, associated with an equally marked susceptibility to tuberculosis, and with reduced fertility. In a family generation the occurrence of multiple carcinomas practically always means that they have occurred in a preceding generation. Moreover, the family tendency is naturally more marked when carcinoma is found on both sides.

However, cancer is so widespread that there must be very few families whose near or distant relatives have not been affected. In fact, Snow³² in 1,075 cases of malignant diseases, including 57 carcinomas, found a history of cancer in the parents in 15.7 per cent; yet of 78 individuals in perfect health, the family incidence was 17 to 19 per cent.

Gneinatz³³ obtained similar results. Of 210 cancers, there was a history of heredity in 18; of 166 benign tumors, a cancerous heredity was given in 11; lastly, in 103 adults without tumors of any kind, there was cancerous heredity in 12. A series of 500 males with cancer of the tongue,

etc., and of 500 females with mammary cancer, at the Middlesex Hospital, London, was investigated from this standpoint by Hill and Tritsch³⁴ and they found that 14.6 per cent of the males, and 7.8 per cent of the females gave a history of heredity.

Menetrier³⁵ estimates that a history of heredity will be given by about 13 per cent of all subjects with cancer. DeBovis³⁶ states that the percentage of cancerous heredity in the Belgian, German, and Dutch collections of statistics in 16.6, 17, and 18.1, respectively. All the foregoing relate to cancer in general, visceral or otherwise, but for squamous-celled epitheliomas alone, Hueriaux,³⁷ of 563 cases under his care, tells us there was a history of heredity in 10.75 per cent.

Before leaving this phase, attention may be drawn to Miss Slye's³⁸ researches on heredity in mice. Since these animals were living under artificial conditions, and since we know so little of life processes in such short-lived creatures, the findings, while interesting, should be accepted with some reservation when discussing cancer of human beings. After an experience with 5,000 individuals, the results show cancer to be hereditary in the strict sense. The common laboratory infections spread through a given cage as well as to adjacent cages; not so with cancer. When an infected mouse dies and is devoured, every mouse in the cage is liable to be carried off by the same infection; this never happens with cancer. Cancer differs so inevitably that it can be manipulated—can be put into a strain, can be extracted out, or can be bred out of a line one side of which carried 100 per cent of cancer originally. Finally, cancer is not transmitted as such, but rather as prone to follow a given provocation, probably in the form of over irritation.

Is Cancer a Constitutional Disease?

The older authors looked upon cancer as the local manifestation of a constitutional disease, a view resurrected recently. Consequently, they propose to treat it by systemic measures—witness mercury by Boerhaave early in the 18th century; and hemlock by Stork later on. Early in the last century, the day of indiscriminate bleeding for every disease in the nosology, venesection was used by Broussais, that "prince of bleeders," and others.

From this viewpoint it was but a step to attribute malignant tumors to various constitutional disturbances. Thus, in 1899, Behla³⁹ gave as his opinion that cancer is a parasitic disease which may be propagated in like manner to malaria. Both these affections bear some relation to damp and marshy conditions. This, it will be noted,

was after the malarial plasmodium was discovered. The following year he enlarged on this view, stating that the water of stagnant ponds or ditches which have forests or undergrowth on their banks is suspicious, and such water with great probability may be regarded as the bearer of the germ. Where cancer is "endemic," it is advisable that only boiled water be used for drinking, for washing domestic utensils, or to water gardens. Since cancer may also be derived from vegetables, salads and raw vegetables must not be washed with water unless boiled.

Boiling water as a prophylactic is also recommended in a pamphlet recently issued by a San Diego physician. He believes that the disease is due to water-borne parasites, and recites the usual arguments. Hence douches convey the germ to the uterus, and so on, though the gynecologists tell us some women go through a long life without ever knowing what a vaginal douche is. The Japanese form a stumbling block to this theory, for the author admits they bathe excessively, yet are little subject. This is accounted for by the fact that only hot water is used for baths, etc.

As a matter of fact, the cancer mortality in Japan is as high as in several European countries. This theory should explain the infrequency among the Eskimos. The anecdote may be recalled of the individual of that race who was given a cantharides blister, which had no effect, for it did not penetrate the various strata of dirt and never reached the skin.

In 1901, Löffler⁴⁰ proposed to treat cancer with injections of blood from malarial patients. Malaria and cancer are mutually antagonistic. Malaria is most prevalent in the tropics, and as it gradually lessens toward the poles, cancer increases, due to the fact that the natives in tropical countries have at some time in life been affected with paludal infections of severe type. Coming from the co-discoverer of the diphtheria bacillus, this is surprising. One of the most malaria-infected spots on the globe is Italy, especially the notorious Campagna outside Rome, yet, as Bertillon, and also DeBovis, show, cancer is rare.

Kieffer,⁴¹ after extensive investigations in Cuba, comes to the conclusion that there is no real antagonism between malaria and cancer, and that the source of malignant disease is not modified by the occurrence of malarial infection in can-

cerous subjects. He has had a varied experience in the tropics, and finds that malignant disease is relatively less frequent than in colder climes, though in this respect countries differ greatly.

One more systemic disease which has been thought to have some etiologic influence is rheumatism. Hislop and Fenwick,¹⁶ in their paper already cited, point out: "So many of the cases were rheumatic, and rheumatism was so prevalent in subacute or chronic forms in bush districts, that we can hardly ascribe the coincidence of rheumatism and cancer to accident." They likewise suggest: "It is not impossible to imagine that the circulation of the blood in rheumatic cases may act as a direct irritant to tissues." Bell,¹⁷ also, claims individuals with a tendency to rheumatism are more liable to cancer of the mucosa. He naturally advocates a non-operative treatment.

Tuberculosis and Cancer

The dictum of Rokitansky that cancer and tuberculosis are inimical to each other has proved to be unfounded, cases of each in the same subject being placed on record from time to time, though, to be sure, the association is not very frequent. While Landis¹⁸ states that of 633 necropsies at the Henry Phipps Institute, a very small percentage not being tuberculous, but one carcinoma was found in fifteen years, and that in patients free from tuberculosis, other institutions give a much larger proportion. Thus Lubarsch¹⁹ in 6,536 cases, found 4.4 per cent of tuberculous individuals were affected with cancer; on the other hand, 20.6 per cent of cancerous subjects had tuberculosis. Bang²⁰ in a series of 6,000 necropsies on tuberculous individuals, found 16 per cent of these had cancer as well; and Boinet²¹ in 800 necropsies, discovered cancer in 35, in 11 of which pulmonary lesions were present.

These figures are for the purpose of introducing the theory of McConkey²² who states that the older writers noticed the striking analogy between cancer and tuberculosis. Since 1882, no one seems to have suspected the tubercle bacillus. As a result of several months' investigation founded on this hypothesis, he is convinced this organism is the cause of cancer by reason of its well known effect of causing cell proliferation. In young and robust subjects, such proliferation is checked, as a rule, by an exudate of lymph as well as lymph cells, which surrounds the new growth and we have a tubercle; but in subjects whose reaction is not sufficient to hedge it in, a cancer is the result.

Syphilis, another member of the infective granulomata, has been incriminated by Curtis,²³ who writes that in the early nineties, among the patients treated for cancer he discovered some

with a symptom which he had demonstrated to be a clinical sign of syphilis, *e. g.*, the egg-skin eschar of the mouth and other mucosæ. He is warranted in the conclusion that syphilis is the real cause, because in the succeeding eighteen years he had found clinical evidence of syphilis in the majority of his cancer cases, and because antisyphilitic treatment improved all cases and even cured some when seen early.

Long ago Turenne²⁴ advocated counteracting the virus of carcinoma by inoculation with syphilis, and we believe even carried it out.

Within the last few months DePury²⁵ has given an interesting account of his experiences in Africa. In 1830 his grandfather emigrated to South Africa as a missionary among the BaSutos, a tribe of Zulus, living near what was afterward the southern part of the Orange Free State. His father became a medical missionary, and in due time DePury himself, fifty years after his grandfather's arrival. In the meantime the habits of the natives had undergone great changes. The communal system with polygamy had given way to monogamy through the efforts of the missionaries. Moreover, the discovery of the diamond and gold mines, with an influx of adventurers from all parts of the globe, led to the introduction of syphilis, which was rapidly spread by the young men of the tribe who worked at the mines long enough to get a start in life.

Our author, who saw several thousand patients in a year in his dispensary, was soon struck with the absence of malignant disease among the natives though occurring in Europeans, and mentioned this to his father. The latter replied: "There is no cancer among the BaSutos; I have been searching for it in vain for twenty-five years." At length DePury saw adenocarcinoma and those rapidly-developing neoplasms which affect principally young individuals with hereditary or acquired syphilis.

A few months after the Boer war he visited the hospitals in his vicinity, and the testimony was unanimous that while syphilis was diminishing in intensity, probably on account of the total syphilization of the race, carcinoma was becoming more and more common. Moreover among the BaSutos cancer affects principally individuals from thirty to forty, rarely those over fifty. The most common forms were the glandular type—adenocarcinoma of the liver, of the bones, and of

the large lymph nodes. Thus in less than half a century an admirably healthy tribe, of magnificent physique, with almost patriarchial customs, as a result of European influence, acquired first syphilis, then cancer, and lastly tuberculosis. A fine example, he remarks sarcastically, of the benefits of civilization.

The author is now in charge of a French military hospital, and quotes Jaboulay, who asserted that any patient developing cancer before the age of twenty-eight was syphilitic. He then had under his care an officer who showed the close relation between syphilis and cancer. The great-grandfather was syphilitic, and died at the age of fifty-eight from cancer of the stomach. His wife, probably infected by him, also died from cancer at the same age. The grandfather, likewise syphilitic, died at fifty-eight from lingual carcinoma, and the grandmother from cancer of the breast at almost the same age. Thus fifty-eight years was generally the fatal age, though the father is now sixty. He likewise is syphilitic, obese, weighing 242 pounds, and is diabetic. The officer himself was syphilitic, entirely bald at thirty-three. The father, from whom the genealogic details were gleaned, stated other members of the family died from cancer, and pithily observed: "With us everybody is either cancerous or syphilitic."

DePury firmly believes not only that syphilis favors the development of cancer, but that the hereditary form is the fitting soil, admirably prepared and predestined, so to speak, to a fatal cancerous degeneration. In conclusion, he remarks it is curious that of the three great plagues which in Europe since the sixteenth century seem to follow and complement and serve as lures for one another, two should be of parasitic origin, the other not.

If there is any foundation for the theory of the syphilitic causation, striking confirmation should be had from the Pacific Islands, which have been a hotbed of syphilis for considerable over one hundred years, as a result of the visit of whaling vessels. Both negative and affirmative evidence is to be had. Kieffer⁵¹ quotes Robertson as stating that cancerous disease is fairly prevalent in the Gilbert Islands, the inhabitants of which are darker than the Polynesians. At Fiji the admissions of the Colonial hospital for cancer in five years numbered four for native Fijians and one for Polynesians; 1.3 and 1.2 per 1,000 admissions respectively (Hoffman⁵¹). The Fijians also are much darker than the Polynesians. At Tahiti, of sixty-one major operations in two years, according to Ortholan,⁵² there was but one for malignant disease, and that was a sarcoma; though in the

Low Archipelago, not far away, of five deaths two were from cancer of the liver and of the uterus. In China, too, Jefferys and Maxwell state syphilis is met with from one end of the country to the other, yet cancer is not unduly frequent. Of 34,197 new cases in the Tung-Kuan hospital the percentage of malignant disease was only 0.5. While they operated on many cases, this is not to be wondered at considering the density of the population there. At any rate, cancer of the alimentary tract, from the cardiac end of the stomach to the last inches of colon, in their experience, is extraordinarily rare.

Kellert⁵³ records a veritable pathologic museum in a woman, aged thirty-nine, syphilis, tuberculosis, and cancer. It was thought the first was possibly eongenital, the tuberculosis comparatively recent, and the cancer (of the pharynx) probably the last to appear.

Before taking up the final section I propose to notice some more or less startling theories advanced by professional, as well as laymen:

It is just about half a century since Moore⁵⁴ claimed cancer is more common in the first-born, though pediatricians tell us the death rate from these in infancy is unusually high, owing to the inexperience of the mothers.

Professor Senn⁵⁵ states in his work on tumors: While mental anxiety may favor the origin of carcinoma by impairing nutrition and thus impairing the physiologic resistance of the tissues, we have no evidence that nervous influences exert a more direct effect. "It is different with dread or fear of carcinoma," he adds. "The writer recollects two patients who for no tangible reason whatever were in constant dread of the disease for many years, when finally their fears were realized. Apprehensions of this nature must certainly exert a positive influence on the etiology of carcinoma." The influence of mind on matter, indeed!

A French author, Noël,⁵⁶ finds certain contagious tumor-like growths are often to be found on the trees in districts with undue prevalence of cancer. He even thinks there is some etiologic relation between these tree "cancers" and the same tumors in man, for the latter are common in persons living in or near woods. . . . Insects have a special preference for the tree "cancers," and carry infection not only from tree to tree, but also propagate it through orchards in food for human beings. Mankind may be thus infected; and when the virus enters by the mouth

the resulting lesions are in the alimentary tract; the external parts, on the other hand, are involved by direct or contact infection. This theory would hardly account for uterine carcinoma. Moreover, he seems to refer to the galls on oaks and other trees; if so, they result from eggs laid by gall-flies, the resulting swelling serving as food for the larvae.

Stuart-Dow⁵⁷, a laryngologist, is responsible for a novel theory. Sufficiently impaired function of the thyroid leads to the tissues being waterlogged, so to speak, with mucin, and the establishment of myxedema. As he has never observed cancer and myxedema at the same time, he suggests an excess of mucin in the tissues may insure against both carcinoma and sarcoma. With thyroid overwork, there must be a lessening of the normal quantity of mucin, both in the tissues and on the surfaces, and he believes this "hypomyxia" is the true pre-cancerous condition.

Bashford⁵⁸ quotes a "distinguished surgeon" as anathematizing the bedclothes and the discharges from cancer patients as dangerous sources of infection.

The first production by a layman to be considered is that the embryologist Beard⁵⁹ of Edinburgh, who is a doctor, though of science, not medicine. His theory, which is his latest work, he informs us was first announced, for cancer in 1902, and for sarcoma in 1904, is that the "irresponsible trophoblast," as he is fond of terming it, is a sort of pathologic I. W. W., and runs wild like an opium-crazed Malay. The best way is to let him state his own case.

"At the critical period, the embryo, complete in all its parts, begins to nourish itself by an alkaline pancreatic digestion, and with a ferment known as trypsin. If this latter be wanting, the asexual generation, the trophoblast, may become a malignant tumor of the deadliest description; in its presence it becomes harmless and slowly degenerates. Clearly, then, since cancer is an irresponsible trophoblast, the ferment which brings about the degeneration of this in normal development ought to possess potency when directed against the cells of a malignant tumor."

While it must be confessed the development of chorionepithelioma appears to uphold his views it seems strange that the pancreas, which is to protect the body by secreting trypsin, should itself be attacked. As for the corollary of this theory, the trypsin treatment, Bainbridge,⁶⁰ gave it a thorough trial at the Skin and Cancer Hospital in New York City, and states emphatically it does not cure cancer.

It is amusing to note how the doubts which beset the profession as to the etiology of certain

diseases are airily brushed aside by laymen. Thus Russell⁶¹ takes us into his confidence long enough to impart the following:

"All countries or parts of countries which use much flesh, beer, tea, coffee, etc., have an increase of cancer. Every country not using these or other irritating substances in excess have little or no cancer. . . . Rheumatism and heart weakness are favorable to the growth of cancer, and these maladies are largely produced by excess of food, and of toxins, such as tea, coffee, alcohol, beer, etc."

He seems to attribute about equal importance to the influence of "toxins," as he calls them, and that of ingesting food at too high a temperature. In this connection he made some observations and discovered that the temperature of porridge was 163°, that of rice 168-176°, and liquids as well as solids are habitually swallowed at 120-170°, quite unbearable for the skin.

This recalls the observation of a medical missionary in China, Maxwell, I believe, that cancer of the esophagus and mouth is quite common there among the men, owing, he believes, to eating rice while quite hot; on the other hand, the women who eat later, after the rice is cool or even cold, are but seldom affected.

Green,⁶² of Edinburgh, describes himself as a "former student of medicine." A few years ago he published some papers which now appear in a booklet. In these he claimed cancer is due to some product formed during the burning of coal. He first took up Nairnshire, a county in the north of Scotland, which has the highest death rate in the country in the rural districts, while the town rate is normal. Of the four registration districts, the cancer deaths were: 57, 13, 15 and 1, respectively. This last was a rodent ulcer, in a patient aged eighty-one. The reason for the low rate he believes to be that only peat is burned. He claims malignant disease is unknown in Greenland, where only oil is burned, but this is not quite accurate, as will be seen.

Later he checked his results by similar investigations in the Orkney Islands. Here the fuel is either peat or coal or a mixture, since there are no forests. Now in the districts where peat only is burned, cancer accounts for one death in 42; where coal alone is used, the proportion is 1.9. However, he found three districts where the death rate was very high, though peat was the universal fuel. These results seemed unaccountable until the peat was analyzed when—though it

was supposed to contain no sulphur—it actually showed 1 per cent, considerably more than in many specimens of coal. Green believes cancer production hinges on the sulphur in the fuel. Sulphur dioxid must be given off when sulphur is burned, and it is some compound of the dioxid which sets up cancer. In this connection, though not exactly germane it may be recalled that many years ago Webb²⁰ proved that coal miners in England are practically immune to cancer.

The last layman whom we shall quote, as well as the latest, for his booklet appeared in 1917, is Lieutenant Colonel Hildebrand,²¹ late of the Indian Army. It is well known that retired Indian officials are peppery and our author is no exception, for, failing to have his theories accepted by the profession, they should be "carefully sifted by a Royal Commission composed of judges, directors of life insurance companies. I would suggest that no doctors or so-called experts be allowed to be members of the Royal Commission." His views are that cancer is caused by drinking unboiled and hard water, which in due time hardens the lining of the alimentary tract. Given this fibrous tissue, cancer may occur if radium lodges in it. The radium in turn is derived either from the rocks whence the hard water is obtained, from lead pipes, or the corroded surface of boilers, etc.

Lead is believed to be one of the end-products of radium, not its source. Hildebrand is by no means niggard with his theories, for another one is that bread made with yeast from fermented spirit renders the individual bad tempered, though if made from brewer's yeast, it soothes them.

Influence of Diet on Cancer

The large subject of diet has been left mostly to the last because the vagaries of some of its proponents can be better understood by what has gone before, and because this theory carries with it some subtheories which cannot very well be considered apart.

So far as diet is concerned, is it some excess as a whole, or of some particular article of food, or of some adjuvant or condiment? Here there is a decided discrepancy of opinion.

The investigation on apparently the largest scale was carried out in 1911 by Bertillon,²² the celebrated chief of the Paris Bureau of Statistics. He drew up a map of France, with two squares, each about one-third of the whole country. One, which embraces practically all of northern France, had a death rate two, three, or four times higher than the other on the south. The first much resembles the map showing the greatest consumption of alcohol, though Brittany, which is notorious for its excessive consumption, is outside. He

also points out that, generally speaking, countries bordering on the Mediterranean have about half as many cancer deaths as those further north in Denmark, Holland, etc.

Bertillon remarks that with so sharply marked a geographic distribution there must be a cause, a single one, which preponderates over the others; but this he was unable to discover. In Paris, the increase in mortality is only in cancer of the stomach and rectum. Cancer of the mouth and breast have not increased. Those of the female genital organs are even diminishing.

Therefore, the causes are special to the digestive tract, except the mouth. Is there some article of diet more used now than formerly which causes the increase? Is it this food which affects the country in the north more than the remainder? Is it meat and, if so, some particular kind? More meat is eaten at present, and more in the north than in the south of France. He tabulated the cancer frequency for a decade in forty-seven towns and the amount of meat consumed, and found that of sixteen using little meat and having but few deaths, only two are within the fatal square.

The lower death rate among Jews has been attributed by Fishberg²³ to some peculiarity in their ritual laws on diet. As regards the non-use of pork, cancer, with the exception of carcinoma of the penis, is frequent among Mohammedans, who also abstain from pork. This exception is generally agreed to be due to circumcision. The Imperial Cancer Research Institute collected a number of examples among the Arabs of Khartoum.

While the Jewish race is less subject to cancer, it is by no means exempt. The late Sir B. W. Richardson,²⁴ of London, said he had noticed it comparatively frequently among his well-to-do Jewish patients. Bainbridge²⁵ also states he has operated on many cases and refers to a specific instance, but it was a sarcoma. Theilhaber,²⁶ at the International Cancer Conference, reported that cancer is relatively frequent among the Jews in Munich, though carcinoma of the uterus is decidedly uncommon.

Kalgouf²⁷ has even recorded what may well be termed a cancer "epidemic." In a small town with 1,500 inhabitants, 600 Gentiles, within a year he treated eight cases, seven in Jews, and but two with a history of heredity. During the previous twelve years he had not seen more than seven or eight cases altogether.

²⁵ Bosc, F. J.: *Presse méd.*, November 26, 1913.

has considered the influence of diet from a different point of view. In 1898 he stated that he believed cancer was due to protozoa, and, five years later, that affections supposed to be due to ultra-microscopic causes are, as a matter of fact, produced by protozoa. As the result of investigation of an enormous number of cancers, he claims in his latest paper to have found protozoa in all, but in different stages of development.

The prevalence of cancer is accounted for, in his opinion, by the widespread of protozoa in nature. The sporulating, or resisting, forms are excreted in the feces of insects, and of most of the animals, both cold and warm blooded, associated with human beings or used as food. If dust laden with the feces of any animal serving as a host becomes lodged on the lips, or if an insect is crushed on the skin, a portal is opened for protozoa. Thus, he continues, the gastrointestinal tract is prone to constant traumata, especially since fish, mollusks, etc., used for food have hard parts which serve both as a vulnerating agent and as a mode of infection. He accounts for the great frequency of cancer in the alimentary tract by the use of raw or partly cooked vegetables and fruit, fish, or flesh. In some parts of South America, e. g., Uruguay and Argentine, cancers of the esophagus, stomach, and intestine are very prevalent, said to be due to an excessive flesh diet.

After his pronunciamiento, already quoted, Russell⁶¹ apparently has some misgivings, for he adds: "Flesh eating in itself, apart from excess or common adjuncts, is certainly not a large contributing cause, for the very moderate flesh-eating peasantry of Normandy, Norway, Switzerland, South Australia, etc., have about the highest rates of all."

For many years Bulkley⁶⁰, the well known dermatologist, has been of the opinion that eating of meat produces cancer, and states he has treated both primary and recurrent cases by strict vegetarian diet with—so he claims—remarkable results. He likens carcinoma to psoriasis, which is characterized by epithelial prolongations into the corium quite comparable to the ingrowing masses of cells met with in the early stage of cancer. Again, cases of epithelioma developing from psoriasis are seen not infrequently. He has placed a number of cases on record where the lesions have disappeared entirely without any medical measures whatever, merely a strict vegetarian diet. In a somewhat extended tour of the far East, during which hospitals in Japan, China, and the Philippines were visited, with a total of many thousands of patients, he was told that "cancer was rarely seen among vegetarian peoples."

Nevertheless, cancer is not rare in Japan by any means—60 per 100,000 population; and as for the Philippines, or at least Manila, Dudley⁷⁰ states that of 4,284 admissions to St. Paul's Hospital, 48 were for carcinoma, and 17 for sarcoma; while 27 cases of carcinoma and 8 of sarcoma were inoperable. The total deaths in the city for the year were 7,613, of these, 64 being due to cancer. Kieffer⁷¹ also states that cancer is not uncommonly rare in the Philippines.

Bell⁷², about the same time as Bulkley, advised a diet of uncooked food, nuts, vegetables, with complete avoidance of meat.

One of the earliest advocates of the meat theory was the late Sir W. M. Banks, of Liverpool, in a discussion some twenty-five years ago.

Hoffman⁷³ remarks: "If meat-eating, as such, were a definite cause of cancer frequency, the disease would be exceptionally common among tribes of our Indians who, to an unusual extent, live upon a meat diet. Yet of 886 deaths reported to the Census Bureau, only 9, 1.02 per cent, were from malignant tumors."

Another race which should be ravaged by cancer, on the meat hypothesis, is the Eskimo. Travelers tell us that practically the only vegetable food they obtain is from the partly digested remains of muskox and reindeer, with some scanty supplies of scurvy-grass, and so on. Yet they seem immune, though a few deaths are reported by the Danish official physicians stationed in Greenland for many years past. Meldorf⁷⁴, for example, states that of 15,000 patients, less than 1 per cent had tumors, only a few of these being malignant.

The increasing prevalence of renal calculi in Switzerland has been attributed to diet also by Lardy⁷², while this topic is foreign to our subject, his opinions may be briefly referred to as showing the extreme views often held. After residing in Turkey for many years, he was struck on his return to Switzerland by the greatly increased frequency of kidney stones, and suggested this was caused by the much freer use of mutton. In 1880, about 1,650 tons were eaten, while in 1911, the date of his paper, the amount had grown to nearly 8,000 tons. He claims that in other countries, such as Turkey in Asia, Russia, Hungary, and England, where there are many calculi, the inhabitants also consume large quantities of mutton.

Ochsner⁷⁵, however, observes that India and China are two countries where stone is most common. India probably has the most cases, and an

⁷³ Ochsner, A. J.: General Surgery, Practical Medicine, Series 1918, ii, 540.

English author remarks, "one might build walls of calculi." Yet the Hindus are vegetarians, as are the Chinese. The frequency in England is confined principally to the eastern counties where it is supposed to be due to the hard limestone water.

In the English colony of Sierra Leone, west coast of Africa, Renner⁷⁴ finds the number of cancers, especially of the breast, increasing among the "creoles" or descendants of liberated slaves due, he believes, to indulging in preserved and imported foreign fruits, sweetmeats, etc. It is absent or rare in the aborigines who live on their primitive food.

It is a disturbance of the potassium balance of the body which is responsible, so Ross⁷⁵ claims. The spread of cancer is caused by the growing deficiency of potassium in our food and drink.

One of our common condiments is to blame, according to Robinson⁷⁶, who in his somewhat recent articles gives figures to prove that the cause is to be found in the constitution of the blood plasma as evidenced by the frequency with which such organs as have free blood supply are affected. The improvement, as a result of vegetarian diet, is due to the absence of common salt. Meat must be salted more than is normally found in the flesh of the animal, though meat contains a much higher percentage than ordinary vegetables. Salt must ultimately find its way into the plasma, increasing its saline content to a higher degree than the one in which the cells were intended to live normally. To produce cancer, the subject must have inherited an antipathy to chlorin which he terms "chlorism," and likens to bromism and iodism, of the same chemical group as chlorin. The hereditary tendency may lie in transmitting this antipathy.

Several Factors Are Concerned

Robinson revives Braithwait's⁷⁷ theory of 1901-2, which was that there are four factors originating the disease. Salt is the essential one, but without one, generally two more, does not operate, the others being excessive feeding, especially meat, senility of the cells, and local irritation. All four of these may be present. The freedom of the Jews is due to their not eating bacon. Cancer houses prevail where there is room to keep a pig, and the habitants eat bacon, etc.

At the Cancer Conference, Schöne⁷⁸, of Marburg, also stated that sodium chlorid in large quantities seems to favor the proliferation of tumors.

According to Hewlett⁷⁹, on the other hand, the death rate among sailors and fishermen who use large quantities of salted provisions is only 60

and 46 per 1,000, respectively. Moreover, many of us can remember when salt meat formed a large proportion of the diet in rural communities. This is largely a thing of the past; indeed, in the last thirty or forty years the facilities for obtaining fresh meat have already lessened the usual consumption of salt meat, yet cancer is increasing by leaps and bounds.

Of course, alcohol, too, has been dragged in, the late J. F. Payne⁸⁰ alleging this as a factor in 1899. If we remember correctly he was the medical referee for a temperance life insurance company. Any attack on his habits of eating and drinking perturbs the wellfed Englishman, and we are not surprised at the following utterance from Mr. Owen⁸¹:

"In these days when well-meaning but overzealous persons are forever telling us that the chief part of our illnesses are brought on by our misdeeds, and especially by a moderate indulgence in what they are pleased to call "alcoholic beverages," it is somewhat of a comfort to find that the trout and carp, undoubtedly water-drinkers, are, with the rest of us, liable to cancer."

In fact, Heron⁸² of the Galton Institute (London) actually found cancer less common among inebriates than in the population at large.

Biologic Phenomena

Such are a few of the many theories to account for this fell disease. Some are absurd, others ridiculous; more than one are diametrically opposed to others, yet several seem to contain a figment of truth. Some facts can be found to substantiate the parasitic theory, others as the famous "Kangri burns" of Kashmir, negate it. This leads me to ask if there is only one cause after all. As Rohdenburg and Bullock⁸³ observe, the wide distribution of tumors in nature speaks for the possibility they are dependent on general biologic phenomena, as opposed to some specific casual agent.

Cancers have been found in the warm-blooded animals and birds, in the cold-blooded reptiles, amphibians and fishes, and—according to Bashford⁸⁴—even the lowly oyster has been found to harbor a tumor. I believe it is evident that the same cause for malignant tumors in man must also hold good for similar growths in other vertebrates.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

RECONSTRUCTION THERAPY. By William Rush Dunstan, Jr., M.D., assistant physician at Sheppard and Enoch Pratt Hospital, Towson, Md.; instructor in psychiatry at the Johns Hopkins University, president of the National Society and of the Maryland Society for the Promotion of Occupational Therapy; secretary of the Maryland Psychiatric Society.*

As one who had had long training and experience in the specialties of administrative work in hospitals, clinics, and the educational features connected with them, the author surveys the field of reconstructive therapy in a thorough, orderly, and complete fashion. He shows the relative value of the various mediums of restorative treatment; the avenues of reconstructive training and treatment; physical education involving occupation and occupational therapy; vocational reeducation; workshops; prosthetic appliances and occupational therapy for special classes of patients.

The chief worth of the book, however, is in the suggestive helps which it offers to occupational directors and their aides. Chapters are devoted to the qualifications essential to success for the occupational director, and his duties in state hospitals, incorporated hospitals, psychiatric clinics, and in general hospitals. A bibliography of occupational therapy is appended to the book.

THE DISABLED SOLDIER. By Douglas C. McMurtrie, director, Red Cross Institute for Crippled and Disabled men; president, Federation of the Associations for Cripples; editor, American Journal for Crippled Children. With an Introduction by Jeremiah Milbank, vice-chairman, Committee of Direction, Red Cross Institute for Crippled and Disabled Men.†

The viewpoint of one who has devoted the years of his professional career largely to the cause of the cripple, is the prime element of worth in this book, and is the quality which distinguishes it from every other work on the subject of rehabilitation for the disabled.

The book may be likened to a series of sketches taken from the histories of armies and nations of other centuries. It traces the social conception of the cripple's place in the world from the time when deformed men and women were looked upon with loathing and scorn by their healthy neighbors, who held to the superstition that a deformed person was possessed of an evil spirit.

The successive measures adopted by armies and governments during the Middle Ages for the pensioning and maintenance of disabled soldiers; the evils; the injustice; the persecution and pauperism; the almsgiving; the shiftlessness; the denial of the cripple's equality with other men, and the refusal of modern industry to accept the labor of disabled workmen, are related by the author.

The closing chapters give in perspective the new conception of the duty of governments to insure restoration and rehabilitation of its soldiers or disabled workers.

The title of the book suggests the timeliness of Dr. Mc-

Murtrie's contribution rather than its true scope and significance. He has given expression to the principle that has been recognized only in recent years, that rehabilitation of disabled members of society is a duty which is wisely economical and broadly humanitarian in its application.

THE REDEMPTION OF THE DISABLED. A Study of Rehabilitation for the disabled of the War and of Industry. By Garrard Harris, Research Division Federal Board for Vocational Education. With an Introductory Chapter by Frank Billings, Col., M. C., U. S. Army; Chief of the Division of Physical Reconstruction, Office of the Surgeon General; and a Foreword by Charles A. Prosser, Director of the Federal Board for Vocational Education.‡

What may properly be defined as a statement of the newly conceived principle in the political and social life of modern nations is the theme of "The Redemption of the Disabled." The author does not in any place state his theme concisely, yet the reader is conscious of an idea which has sprung up during the war and since, that states and governments must look to the rehabilitation of all the crippled and disabled members of the social body.

This principle conceives of the restoration and rescue of every victim of accident in industry, and every sufferer from occupational disease or physical impairment caused by any of the processes of industrial enterprise. The book is a narrative of the advance and growth of the vocational and therapeutic measures employed by the Army Medical Corps and the Federal Board for Vocational Education in restoring disabled soldiers, sailors, and marines to health and independence.

The author endeavors to state a proposition that contemplates action by the health departments and legislatures of the states. He contends that the problem of taking care of the industrial workers must be dealt with by the states and the Federal Government, and that some permanent policy must be worked out in every state that has an appreciable class of workers in industry. The newness of the problem, when considered as an issue for state action, hinders the writer in giving a well-defined statement of the principle, but furnishes an excellent starting point for further steps toward that end.

ATHLETES ALL. Training, Organization, and Play. By Walter Camp.§

While written for the general reader, this book still possesses exceptional features of interest to professional men and women who are interested in welfare and health activities of any kind. The healthy sports of the track,

Every Requirement Met In the Use of Tile

For practical, sanitary purposes, as well as decorative values, in the factory, school, hospital, public institution, public bath, swimming pool, etc., tile is the all-service material.

Its range of colors and its flexibility of treatment make it most adaptable and attractive. It is safe, because non-absorbent, and therefore capable of resisting the germs of disease.

Tile is naturally clean, and is easily kept clean. The heads of institutions of all kinds appreciate these qualities in a constantly growing degree. The popularity of tile—old as it is in serving mankind—was never so great as it is today.

This association offers a helpful service to all who may have use for tile.

SUBSCRIPTION

Domestic postage, \$3.00. Foreign postage, \$3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS. Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS. Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

SUBSCRIPTION BLANK

BOOKS OF THE MONTH

(Continued from Page 368)

the field, and the gymnasium are a means to national preparedness both for the defence of the nation and for the preservation of American ideals. The author discusses organization and management for the furtherance of games and athletics in schools or camps. Duties of manager and captain are explained, and suggestions offered as to how to conduct an athletic meet. The various sports of the track, gymnasium, and field are given special attention. One of the best chapters in the book is that entitled "Keeping Fit in Winter."

THE WHOLE TRUTH ABOUT ALCOHOL. By George Elliot Flint, M.D., with an introduction by Dr. Abraham Jacobi.*

This book is a rather impassioned plea for the reinstatement of alcoholic beverages in popular favor. The author, a physician, presents in an interesting manner the point of view of those medical men who regard the use of alcohol in moderate amounts as beneficial in sustaining the health and courage of a burdened race.

That alcohol will sustain the strength and vitality of one otherwise below par; that it will carry him through to a good old age and enable him to bear the strain and burden of a complex modern life, are the claims advanced by the author.

The place of alcohol in industrial communities; its use by the working-men; its use in war; in the tropics, and for preventive purposes, are reviewed, and a defense of alcohol established on the ground of the usefulness which may be claimed for it in many ways.

Addenda are included, which are, namely, "Alcohol Economically and Practically Considered" and "Cardinal Gibbons on the National Prohibition of Alcohol."

VEGETATIVE NEUROLOGY. The Anatomy, Physiology, Pharmacodynamics, and Pathology of the Sympathetic and Autonomic Nervous Systems. By Dr. Heinrich Higier, of Warsaw. Authorized translation by Walter Max Kraus, A.M., M.D., New York.†

This author takes up the origin and elaborates on the various functions of the vegetative nervous system, otherwise the sympathetic nervous system, its relations to metabolism, to the endocrine glands of internal secretion, and also its relation to the mind itself. That this system is being considered more carefully and shown greater consideration in the treatment of nervous and mental cases is the strongest evidence that scientists are opening up avenues of thought in such connections as to attract and educate the clinician. The work has been well translated by Doctor Kraus.

EFFECT OF DIET ON ENDURANCE. By Irving Fisher, Professor of Political Economy in Yale University, Chairman of the Hygiene Reference Board of the Life Extension Institute.‡

Professor Fisher's book is a new edition of a study originally printed in the "Publications of Yale University," *Transactions of the Connecticut Academy of Arts and Sciences*, Vol. XIII, pages 1-46, May, 1907. The book contains tabulations and texts giving the results of endurance tests conducted during 1906 among a group of students who formed themselves in an eating club. Rules were established in an endeavor to encourage thorough

Food Cells *All Exploded*

Puffed Grains are steam-exploded grains.

Puffed Wheat and Puffed Rice are whole grains puffed to eight times normal size.

The process was invented by Prof. A. P. Anderson, formerly of Columbia University. The object is to make whole grains easily and completely digestible.

Each kernel of wheat contains some 125 million food cells. Each cell contains a trifle of moisture. In our process we change that moisture to steam, then explode it. We cause in each kernel over 100 million explosions.

No other cooking process breaks half so many food cells as does this.

This is the ideal form in which to supply whole-grain nutrition. And the most enticing form. These bubble grains, toasted, flavorful, flimsy, taste like food confections. Yet they are nothing but whole grains.

(Continued from Page 22)

mastication of food, choice of food by instinct, and by the use of reason when instinct was in doubt. The dishes selected were noted and a record kept of the kinds of foods eaten and the nutritive value in portions of one hundred calories, each portion of food being the equivalent of one hundred calories. The changes in physical endurance as determined by repeating a series of gymnastic exercises at intervals and measuring the relative effort put forth, showed that endurance increased when the proportion of protein in the diet was reduced. By a method of natural selection intended to regulate the diet of the men without imposing restrictions upon them in the choice of food, it was discovered that at the beginning of the experiment the amount of protein used varied greatly, while at the end it was reduced to a fairly uniform level for all the men, whose endurance in each instance was much improved.

THE GIRL IN INDUSTRY. By D. J. Collier. With a Foreword and Introduction by B. L. Hutchins.*

A high standard of health was found to prevail among groups of English working girls wherever there prevailed wholesome conditions at their work, in their home surroundings, and in their opportunity to enjoy the ordinary comforts of life without the handicap of mitigating circumstances. The investigation reported in the present volume was undertaken to secure information as to the biological effects of employment of girls and the future effect on the mature women and their offspring under the conditions of industrial employment in the adolescent years. The greater part of the material presented by the author is based on opinions derived from personal observations, with limited scientific data and no statistical foundation.

THE CONTROL OF THE DRINK TRADE IN BRITAIN. A Contribution to the National Efficiency during the War. By Henry Carter. With a Preface by Lord D'Abernon. Second Edition.†

The outcome of regulation of traffic in intoxicating drinks by the British Government during the war is set forth with completeness and in detail in this study of the subject. Considerable appreciation of the book in England has resulted in demand for a second edition.

The prefatory note by Lord D'Abernon explains the political necessity for a choice by the Government between control of the liquor trade and prohibition. It was the consensus of opinion that regulation and control would accomplish the desired results during the period of the war, and would possibly prove more instructive and satisfactory in operation than prohibition. With this in mind, the volume is of especial interest to the American reader because of the contrast in policies adopted by the two countries.

The new edition has been amplified by the inclusion of statistics to show the decrease in drunkenness, deaths from alcoholic diseases, and crime, following the enactment of the English law. The author notes that considerable dissatisfaction and unrest was produced among the working people of certain industrial communities as a consequence of a shortage of liquors at various times during the war. He reviews the experiences of England in the light of Sweden's experiment under a National system of spirit rationing.

We Can Help Each Other

What special problems confront you in connection with civic and industrial medical and welfare work? If you desire advice in connection with organization plans, if you would have certain information regarding the forming and conducting of mutual benefit societies, or if you have a municipal health problem which requires special consideration by experts, MODERN MEDICINE stands ready to assist you.

The writers and editors of MODERN MEDICINE have devoted years of time and study to the many factors connected with civic and industrial work so far as health and hygiene are concerned. They will give freely of their time and knowledge in order that readers may better be able to meet special problems with which they are confronted.

Simply state your problem in a letter to MODERN MEDICINE and at least one member of our large organization will give it intensive

consideration and endeavor to render constructive assistance.

On the other hand, you can assist us, if you will.

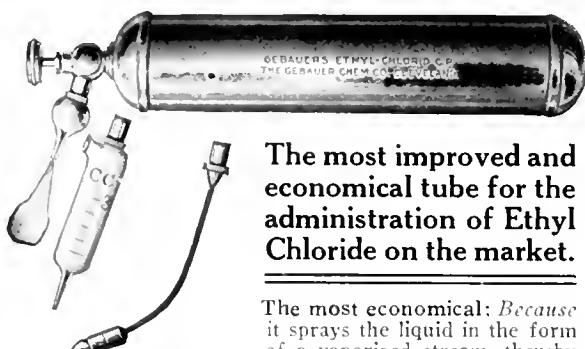

MODERN MEDICINE is ever anxious to keep in touch with results of industrial welfare and medical work, so that the benefits of such work may be made known to its thousands of readers.

In order to complete our survey of the industrial and public health fields, we are desirous of securing the names of all industries doing medical or welfare work among employees. We shall be grateful for any information bearing on the subject and will especially appreciate the forwarding to us of names of physicians and others in charge of such work.

MODERN MEDICINE will be pleased to follow up all leads thus supplied by readers. The small effort required of you may be the means of solving many vexatious problems for others. Will you help?

MODERN MEDICINE

Ethyl Chloride (Gebauer's) Local and General Anesthesia

The most improved and economical tube for the administration of Ethyl Chloride on the market.

The most economical: Because it sprays the liquid in the form of a vaporized stream, thereby hastening evaporation and consequent anesthesia, using 1-10 the liquid used by other tubes. Because the ethyl chloride is put up in a metal tube that will not leak or clog and the liquid is guaranteed to maintain its purity indefinitely.

40 grm tube with ordinary spraying nozzle,	\$1.10
80 " " " "	1.75
Flexible spraying nozzle alone,	.50
Graduated dropper,	.50

The flexible nozzle and the graduated dropper will fit either size tube and can be used indefinitely.

VOCATIONAL TRAINING MAKES SPECIALIST OF DISABLED MEDICAL OFFICER

In its work of rerouting disabled war veterans through courses of training for new vocations, the Federal Board for Vocational Education found a young doctor who had lost his leg in a German prison camp.

Before the war he had been a general practitioner with his sign still rather new, but with a good future. If you can picture the family doctor you know, who sleeps with an eye open, eats with the telephone in one hand, and exercises in and out of an automobile all day and night, you can see that an amputated leg and a constitution suffering from a German prison diet aren't the best qualifications for the job.

He wasn't down-hearted though, and neither was the Board. They got together, and, using the background of medical training, sketched in a special course in eye, ear, nose, and throat at a Chicago medical school, and started in!

Take in his sign? Not much! He's adding to it the twentieth century watchword, "Specialist."

PROTECTS PUBLIC AGAINST CARELESS CONSUMPTIVES

The Iowa Legislature has enacted a law which provides "that if any person afflicted with tuberculosis carelessly or maliciously expectorates the matter coughed from his lungs, and after being warned refuses to protect others against the dangers of his infection, then on complaint filed in writing in the district court the judge may commit such incorrigible consumptive to the state sanatorium, provided there is room, or to any county or private institution for tuberculosis for treatment."

It is also provided "that if a person afflicted with tuberculosis and under treatment at the state sanatorium or county or private hospital for tuberculosis refuses to obey the rules and regulations governing such institution and is a general disturber, then on complaint of the superintendent the district court may authorize such person to be retained in a room or enclosure in such hospital until such person is willing to comply with the rules and regulations of the institution."

ST. LOUIS TO OPEN EIGHT CHILD WELFARE CLINICS NEXT MONTH

Eight clinics to promote the welfare of infants and children of pre-school age will be opened in St. Louis about September 1. Financial support has been obtained for the clinics through the generosity of a group of public spirited citizens.

Supervision of the clinics will be placed under the jurisdiction of the Division of Public Welfare of St. Louis. Medical and nursing service for pregnant mothers and attention for children up to school age is planned. The city will assume the operation of the clinics as a municipal activity in 1920.

The donors are, Benjamin Gretz, Mrs. Lily Busch, Benjamin and Marcus Harris, Mrs. J. Louis Swarts, William T. Hill, Mr. and Mrs. George Warren Brown, Mrs. Ames Cushman, Mrs. Lon A. Hocker, Mrs. A. Breuggemann and an anonymous donor.

The funds will be administered under the direction of Dr. Borden S. Veeder of the Children's Hospital; Mr. John Schmoll, director of public health; Dr. C. H. Shutt, hospital commissioner, and Miss Lyda M. Anderson, chief of the Municipal Nurse's Corps.

Supplementing the Splendid Work of Physicians, Public Health Officials and Welfare Workers in a Practical Way

IN half-a-hundred ways the civic, industrial, health and welfare workers of the day are unselfishly devoting their best thought and efforts to bettering sleeping conditions in the homes of their communities.

They realize the good health and efficiency promoting value of sound, restful sleep. They know that the health restoring value of sleep is by no means limited to the repairing of bodily wastes or the upbuilding of potential energies of the individual. Also they know that workers who enjoy the advantages of modern sanitary sleeping facilities are blessed with better health, do more and better work, and make better citizens as well.

Many of the foremost advocates of sound, restful sleep—physicians and public health officials in big cities and small towns to whom the columns of the local newspapers are open—have already made the advantages of the right kind of sleep a feature of published "health hint topics," over their own signatures.

Much valuable and helpful data regarding this all-important subject has appeared in the leading medical publications during the past year. Authoritative and unbiased as it is, data of this kind should become a practical inspiration to all who are interested in spreading the gospel of sleep.

As the largest makers of metal beds—the largest makers of beds of any kind in the world—we are glad to supplement the efforts of those engaged in this work by furnishing specific data, leaflets, envelope enclosures, and booklets upon the subject of sleep.

Accurate Diagnosis First

No industrial hospital is complete without the most modern facilities for diagnosis. They must be ever ready for the immediate attention a patient's case demands.

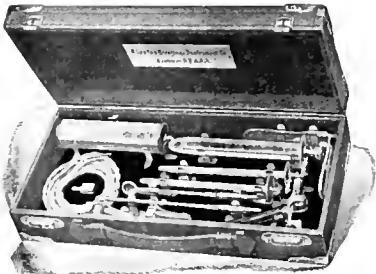

Diagnosis directs the course of treatment and can only be accomplished by the most advanced and approved aids.

For just such attention by the industrial or municipal physician our

MODERN DIAGNOSTIC OUTFIT

is arranged. It contains all the instruments most generally used in urgent cases.

Others will be substituted if desired. Stamp "E. S. I. CO." & guaranty of our manufacture.

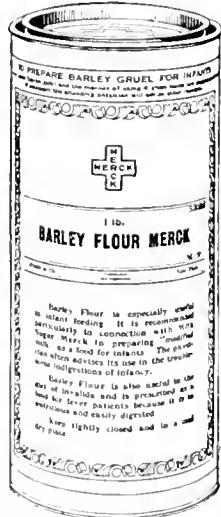

This outfit weighs but 4½ pounds. All instruments can be operated by our battery with adapter or upon direct or alternating current by means of our controller.

Illustrated catalogue sent upon request.

FOURTEEN COUNTRIES SEND DELEGATES TO A. M. A. CONVENTION

Fourteen foreign countries sent delegates to the Atlantic City meeting of the American Medical Association in June. The countries represented were England, France, Belgium, Scotland, Greece, Canada, Cuba, Ecuador, Buenos Aires, Peru, China, Japan, India, and the Province of Cameron, West Africa.

The physicians and surgeons in attendance from those countries were:

Lehman, Wilmer S., Lolodorf, Cameroun, W. Africa.
Caser, Baron Ernest, Belgium.
Depage, Antoine, Belgium.
Duesberg, J., Belgium.
Melis L., Brussels, Belgium.
Nolf, P., Brussels, Belgium.
Sand, Rene, Brussels, Belgium.
Captain Van de Velde, Belgium.
Chutro, Pedro, Buenos Aires.
Aikins, W. H. B., Toronto, Can.
Bagshaw, Elizabeth, Hamilton, Can.
Buchanan, W. D., Peterborough, Ont.
Chartier, Aimé, Sorel, Quebec, Can.
Cleaver, Ernest E., Toronto, Can.

TREATMENT OF SPANISH INFLUENZA

The literature on the so-called Spanish influenza is so voluminous, and the reports of its pathogenesis so varied and conflicting, that it might well be concluded that not one but several epidemics prevailed at the same time. A study made of many French and foreign treatises by Dr. E. Folley,¹ Paris, reveals a constancy of the cardinal symptoms of (1) diminution of arterial tension, (2) irregularity and variation of amplitude of pulse, (3) weakening or even imperceptibility of first sound of heart, (4) early cyanosis of finger nails, (5) enlargement of spleen and slight enlargement of liver, (6) "Sargent's white line," earthy hue of skin, scowling countenance, considerable asthenia, pupillary oscillations, persistent sleeplessness, (7) slight delirium with high temperature, frequently increasing when temperature falls, (8) irritability, in contrast with intellectual torpor, (9) signs of lungs being affected, but in no precise locality, (10) expectoration, in most cases forming with pulmonary localization,

"A NATION OF DYSPEPTICS"

"**Y**OU are a *Nation of dyspeptics*" said a well known English physician, who recently visited America.

"Indigestion is evidently your national disease. You bolt your food, hurry through your meals, and keep your mind on business all the time you are eating. You never more than partly relax during meal time. What is the result?

"Your food is never more than half masticated, insufficient saliva is mixed with it, it lacks moisture, and the food bolus enters the stomach in a condition sure to overtax its digestive powers.

"Indigestion is inevitable, with its train of symptoms ranging from an occasional sense of fullness and discomfort to constant pain and distress."

There is hardly a physician who will deny the truth of this indictment. In the rush and hurry of every day life we have come to look on eating as a necessary habit—instead of a pleasurable event—and so have become a "*Nation of dyspeptics*."

Did you ever stop to think of the value of chewing gum for correcting certain forms of indigestion? Chewing a good pure chicle gum such as Beeman's Pepsin Chewing Gum for fifteen to twenty minutes after eating may be a very simple and common place remedy; it is often as efficient in affording relief as it is convenient and easy to use.

TREATMENT OF SPANISH INFLUENZA

(Continued from Page 28)

frothy, with thin streaks of dull red hue, later changing to whitish or greenish, (11) slight diarrhoea in most cases, constipation in others, (12) urine clear and abundant, never having appearance of so-called "febrile urine," (13) hemorrhage likely to occur in any mucous membrane, and (14) cardiac syncope, preceded by slow and weak pulse.

The constancy of these symptoms, a majority of which occur in each case, and the fact that all characteristics of the disease developed in man after the accidental laboratory inoculation with virus from a patient point to the conclusion that the pandemic was that of a specific disease.

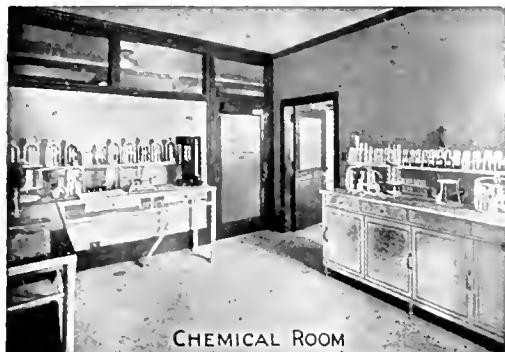

Dr. Folley had frequently recovered from influenza patients a small mobile coccobacillus with bipolar coloration and of a non-adhesive nature, the characteristics of which he promises to describe later. The bacillus generally disappears from the blood when complications exist and a rise of temperature takes place. Colonies of this organism were obtained from the blood of the accidentally inoculated case, and cure was effected by the use of a serum obtained from this group (anti-plague serum). Later it was successfully used with cases showing pulmonary complications and nervous disorders. Used intravenously for patients with syncope and subcutaneously in other cases, not a single death occurred among patients so treated and convalescence was remarkably shortened.

HOW TO START AN INDUSTRIAL MEDICAL SERVICE*

Social organization has always followed the lines of evolution, wherein the cell came first, then a group of cells, then a nervous system; similarly, in the social world first came the family, then the tribe, then the governed nation. New services should be allowed to evolve, and not be forced into existence on plans drawn up in some official headquarters.

The need for an industrial medical service has been dealt with in a previous article; the present intention is to show how it can be started. Its subsequent evolution may thereafter be safely left to the future. The first point to have in mind is that a medical service to be effective should acquire the momentum of popular interest, which can only be obtained through direct touch with the personality of those it serves. This is fundamental, and its absence in the past from public health medicine is some explanation of why the average citizen has taken so little interest in the health of the community of which he is a part, although he is only too ready to discuss personal medical topics. The next point is consideration of the duties to be undertaken. These concern industrial birth, life, and death. Industrial birth is the engagement of workers; and here medical services are of great value. A medical officer acquainted with industrial processes may reject a heart case, a myope, or an incipient hernia for some processes, but safely accept them for others; as he gains more experience he will choose persons for special work according to their capacity as measured by alertness, physique, acuity of hearing or of vision; in short, he will adjust round pegs into round holes, and so do much to avoid the great economic waste of labor turnover, the result of the present method of trial and error which leaves the worker to try place after place until a congenial one is found; by thus examining each newcomer personal contact is established which should never be lost.

SCIENTIFIC—EFFICIENT ECONOMICAL

Pain Relieving Methods

You appreciate the value of sunlight as a therapeutic agency; you know about the pure white rays, the violet rays and the ruby screen. The Sterling Therapeutic Lamp combines all these agencies in an efficient and economical manner.

S TERLING THERAPEUTIC LAMP P

"The Light That Heals"

Has proved one of the most efficient methods of relieving pain; its effect is soothing and analgesic; its rays are germicidal. The warm, soothing, soft rays penetrate and vitalize every cell and tissue, new cell growth is stimulated; the body is refreshed and vitalized.

In rheumatism, neuralgia, neuritis, lumbago, in nervous conditions and a score of other symptoms and diseases, including skin and scalp disease, the Sterling Therapeutic Lamp is invaluable for the relief from pain, inflammation and for corrective purposes.

With stand it is ideally adapted for additional use as a spot light for operations and examinations.

Widely used in sanitariums, physicians' offices and hospitals; special sizes are adapted for the use of patients under the supervision and direction of the family physician.

Write for our interesting Illustrated Booklet showing the various sizes and uses of the Sterling Therapeutic Lamp.

HOW TO START AN INDUSTRIAL MEDICAL SERVICE

(Continued from Page 30)

Industrial life is the period of employment; and here skilled medical services are of even more value; to determine the existence of fatigue, the optimum hours of labor, the presence of faulty ventilation or bad lighting; to supervise the hygiene of workplaces; to arrange for dental supervision; to deal with outbreaks of epidemic disease; to advise on the provision of a canteen and its food-supply, of cloakrooms, of washing facilities, and of suitable overall clothing; to watch lost time and sickness records; to supervise closely the health of those employed on dangerous processes; to organize first aid treatment and establish contact with outside medical treatment; to advise on compensation cases. Here personal contact should be maintained and strengthened, and the medical officer become the friend and adviser of all. Industrial death is the cessation of employment; and here the medical officer should inquire closely into the causation of dismissal or leaving so that he may ascertain where his practice is at fault; such inquiry should be for him what a post-mortem is to the physician and surgeon.

Every industry will have its own special problems; but the above short summary of the work to be done suggests where it must start—viz., in industry by the retention of whole or part-time medical services by employers of labor. The employer will gain in the quality and quantity of output far more than the salary he pays; the worker will benefit by improved health, happiness, and earning capacity. A few employers have already taken this step; and probably more would follow if they could obtain medical men adequately trained, but there are not many who on perusing the above rough list of duties would consider themselves trained to undertake them. Two things are now needed, an increased supply of trained men and an increased demand for their services. The increased supply could rapidly be met by post-graduate courses held at medical schools in industrial areas; Birmingham, Bristol, Cardiff, Glasgow, Manchester, and Sheffield suggest themselves. Practitioners in industrial areas all suffer from lack of knowledge of how their patients earn their livelihood, and would willingly attend such courses. One group of the profession should in this matter take the initiative, both in pressing the schools to start courses and in attending the courses; we refer to the certifying factory surgeons. They already possess a recognized association and are in touch with the factories and workshops; but the duties entrusted to them, as they are aware, are wholly inadequate to the needs of industry.

The increased demand would follow almost automatically from the existence of the supply for each trained practitioner in his daily work would influence the men and their unions on the one side, and the employers and their councils on the other. Both sides would soon appreciate the value of a medical attendant with an intelligent understanding of industrial problems and ready to use his knowledge to their advantage.

Our appeal, then, is to the great provincial medical schools to start post-graduate courses in industrial medicine directed to meet the needs of the district, and so be of direct and immediate benefit to the industries among whom they exist, in the sure and certain hope that the industries in their turn will react and give greater financial support to the schools. The schools need financial support, and it is more likely to be forthcoming if the schools pay attention to the particular needs of industry and establish clearly the value industry will get in return.

NOTES AND COMMENT

AGE AND OCCUPATIONAL DISABILITY

WE PUBLISH in this number a valuable contribution to the subject of the extent of sickness from the pen of Mr. Boris Emmet who was for many years statistical expert for the United States Bureau of Labor Statistics. The figures which he presents in his article are the result of a thorough-going actuarial investigation by the Bureau of one of the leading sickness insurance companies in the country and to date is the most authoritative statement of disability by age and occupation that has appeared.

It has, of course, been evident to all observers that sickness increases with age, but the exact measurement of this has never been given, and it has been a matter merely of impression. Here we find presented with cold analysis the fact that beginning with the age group 45 to 49, the extent of sickness is progressively on the increase. The figures are indeed so clear that they do not need explanation or comment. It is found also in the figures that beginning with the age group 50 to 59 the number of disability days for each person disabled also rapidly increases, showing that the older men recover more slowly from disability.

Even more important in the presentation of his data are the statistics relating to occupational causes. The society insured men in many occupations. It was found that the average number of days lost for all occupations was 6.61 days each year. Certain occupations had a disability rate as high as 9.7, while others had as low a rate as 2.6 days each year. It should be noted, however, that some of the highest disability rates are partly due to the inclusion of industrial accidents which

were particularly heavy among such occupations as mining and freight handling.

The conclusion is unmistakable that there is wide variation in the amount of sickness borne by workers in different occupations. Freight handlers, for instance, suffered 47 per cent more than the average, although the average age of this group was three years less than the average age of the total. At the opposite extremes the professional workers suffered 56.1 per cent, jewelers, 43.9 per cent, and trade and clerical workers 30.3 per cent less than the average. Comparisons, of course, must take other elements into consideration. The living conditions of different groups are different. The intelligence of the groups varies. The wages and consequent ability to obtain a decent living varies and the hours of work are also different. But it can readily be seen by measuring certain occupations with other occupations in which conditions are very similar that the factor of occupation is a steady one as a cause of sickness.

THE VALUE OF MEDICAL STATISTICS IN HOSPITALS

THE physician in chief of the Peter Brent Brigham Hospital of Boston makes some interesting statements regarding medical statistics in the recent report of the hospital. After inserting the usual tables of statistics, he made the following comment: "The value of such tables as well as the value of a considerable part of the statistical report of the superintendent, such as those parts showing occupation of patients, nationality, etc., seems to me slight. They contain

numerous unavoidable inaccuracies. They are too incomplete in some respects. For example, the fact that we treated forty-seven carpenters is the diseases of no practical value. If we stated what diseases these carpenters had, it might be of help as showing the diseases carpenters are liable to and help in their prevention. Here again to be of use, one should know the working conditions of these carpenters, for there is much variety in the work of carpenters. In other words, statistical tables present too incomplete a study to be of much service, if of any. The same is true of other features of these tables. I do not believe much use is made of them, and I consider that their space could be used to better advantage, or at least money could be saved to the hospital by their omission."

Recommendation is made that the data be compiled and published at five-year intervals. The criticism in the report may be misleading. The physician in chief was criticising the inadequacy of existing statistics rather than statistics as such. It is probably true that much of the statistical data, in small hospitals at least, is not used or cannot be used to any particular advantage. This may be because the data is not full enough and does not tell the whole story, or it may be that the number of cases is not sufficient for analysis. The criticism should be taken as a basis for revising case records and statistical data, so that the tables will tell a true story and so that all unnecessary data may be omitted. Time should, of course, not be taken to keep records which cannot be used, or when used can serve no definite purpose; but time should not be spared in the keeping of records and statistics on matters that can be interpreted only by the use of mass data.

AMERICAN HOSPITAL CONFERENCE

ON APRIL 21, 1919, representatives of eight prominent national societies met in Chicago for the purpose of organizing a union to promote the development of American hospitals. The organizations represented were: American Hospital Association, American Medical Association, American College of Surgeons, American Nurses' Association, American Association of Hospital Social Service Workers, Association of American Medical Colleges, Catholic Hospital Association, and the Federation of State Medical Boards. The first fruit of the new union is the American Hospital Conference, in which all of the organizations named will be equally represented, and which four additional organizations, namely, the American Association of Industrial Physicians and Surgeons, the United States Public Health Service,

the Medical Department of the Army, and the Bureau of Medicine and Surgery of the Navy, have already been invited to join.

The new partnership is one which should never be dissolved. Each of the constituent societies is in a position to make—has, indeed, already made—notable contributions to hospital progress. The activities of all of the societies will hereafter be stimulated by periodical conferences, and in place of the old patchwork program there will be introduced a rational design by means of which hospitals will be fitted to the country's needs.

What are some of the things that the American Hospital Conference may be expected to accomplish?

The functions of the various necessary types of hospitals will be defined.

The relations of the hospital to the community will be clarified.

Hospital finances will be expended to better purpose and the expenses of hospitals will be more equitably distributed.

Official hospital inspections will be made to dovetail perfectly.

Hospitals will be taught when to act independently, when to cooperate, and when to combine.

Hospital trustees will acquire a keener and fuller realization of their responsibilities in the training of physicians and nurses.

Wise and uniform legislation will be enacted in several states regulating the training of medical students and of nurses.

The output of fully trained nurses and of trained attendants will be made to measure up to the country's need.

There will be a more general acceptance of certain indispensable standards of work and equipment which have been ably, but not always successfully, advocated by the American Medical Association through its Council of Medical Education, by the American College of Surgeons, by the American Nurses' Association, and the American Hospital Association.

Medical men who have not heretofore concerned themselves with questions of hospital organization and administration will be induced to do so and in consequence the determination of vital questions of hospital policy will no longer be left to laymen who are unfamiliar with the fundamental principles involved.

The purpose of medical social service work will be clearly defined; hospital social service will be standardized and improved. Means will be found to develop adequate facilities for diagnosis and treatment not only in the cities where the task is comparatively easy, but in rural communities for which new facilities must be devised.

Each of the constituent organizations of the conference will have the strong moral support of all of the others. An authoritative center will be established for the guidance of public officials who are concerned in hospital administration, of legislators, and of men of means who desire to benefit the community through donations to hospitals.

The first annual conference will be held in Cincinnati in connection with the American Hospital Association, September 10 to 12, 1919.

MEDICAL CULTS

THE report of the Council on Medical Education of the American Medical Association on medical cults ought to have a wider circulation. It is a brief statement, but it covers the ground and it sets forth the issues involved in the legislative assault made annually by the medical cults on the standards of medical practice. MODERN MEDICINE is pleased to quote the report in full:

"An important matter, which affects the relationship between the public and the practice of medicine and which is a problem directly concerned with medical education and medical licensure, is the existence and practice of the various pseudo-medical cults, represented by osteopaths, chiropractors, naprapaths, spondylotherapists, neuropaths, psycultopaths, etc. Most of the teaching institutions turning out such practitioners have been inspected by the Secretary of the Council while on his various tours of inspecting medical schools. Files of information in regard to these institutions have been kept, which include catalogues, printed literature, circular letters, inspection reports, etc. The problem has been given sufficient study so that the following reliable statements can be made:

"(a) The only logical argument to be made against practitioners of these cults is their lack of education. Such training as they have received has been in institutions requiring little or no educational qualifications for admission, and under faculties made up almost entirely of those who have not had a complete medical training. Graduate nurses could, with far greater justice, ask the right to treat human disorders than could the followers of these cults, because nurses are largely taught by physicians and secure their training in hospitals where all types of disease are treated by physicians.

"(b) Before the recent improvements were made in medical education, many of the medical schools were very little better, from the standpoint of buildings, equipment, and teaching facilities than the better pseudo-medical cult institutions. In the former, however, all instructors

were those who had received a training in all the branches of medicine. Under the greatly improved conditions brought about in the last fifteen years, there is now so marked a distinction between the education and training of physicians as compared with the cult practitioners, that any intelligent layman can note the difference.

"(c) The medical profession is justified in objecting to the various cults, not because of their peculiar systems of practising, but because of their serious lack of education and the fact that they are seeking the right to practise as physicians without meeting the same educational standards with which physicians have to comply. If such practitioners wish to appear before the public as physicians and surgeons and to assume all responsibilities of such, then they should not object to being measured by the same standards and submitting to the same tests.

"(d) The work of the Council in connection with low grade medical colleges, drugless cult institutions, and diploma mills has called attention to the lack of adequate safeguards over the chartering of educational institutions in the various states. In all but a few states any group of individuals for a small fee can secure a charter to open an educational institution and to grant all the degrees in the category, no questions being asked in regard to ability, financially or educationally, to furnish the education usually required for such degrees."

GROWTH OF THE HOSPITAL IDEA*

FIGURES in a recent official report to the U. S. Department of Labor show the astounding growth of the hospital idea in this country during the last half-century. In 1873—less than fifty years ago—there were in the United States only 149 hospitals; today there are nearly 9,100—an increase of nearly 6,000 per cent in the number of institutions. In 1873 the total bed capacity of the then-existing hospitals was 35,453; today the hospitals of the country have a total capacity of approximately 869,000 beds—an increase of over 1,000 per cent. The amount of money at present invested in these institutions is roughly estimated at nearly two billion dollars; the annual expenditure for supplies, equipment, upkeep, and new construction is about three-quarters of a billion.

There is much that is interesting in these enormous totals. Certainly, stronger testimony could be adduced to show that the people of the United States are more converted to the hospital idea, and do not mean to be deprived

of the benefits of hospital care. So far, this is good.

Sober second thought, however, discovers some rather formidable questions in this staggering mass of figures. How much of this vast hospital investment has been wisely made and how much of it is destined to be a dead weight on the development of the future? In how many cases have the needs of the community been carefully surveyed before the hospital was even planned and in how many cases has the plan scarcely gone beyond the feeling, "A hospital is a good thing. Let's have a hospital." A two-hundred-and-fifty-bed maternity hospital is erected, and by the donor's will devoted in perpetuity to this single use, in a community in which the total annual births would never keep the beds filled; a four hundred-and-fifty-bed epileptic colony finds less than a hundred inmates; and meanwhile other institutions are forced to turn patients away. Here and there is a general hospital equipped with an elaborate and costly operating room, but inadequate laboratory facilities, in a community in which surgical cases are few but cases of typhoid and malaria abound. Hospitals to this extent victimized by the misdirected benevolence of their founders are rare, it is to be hoped; yet, on the other hand, the idea that a hospital is a hospital is so general that hospitals carefully adapted to the needs of the communities which they are intended to serve are probably not very common. Everyone realizes that a shoe may be very well made, of the best material, and according to the best designs, yet totally unsuited to the size and shape of a given foot and to the use desired. The principle that a hospital should be as carefully fitted to the needs of a community as a shoe is to the foot is new, however, that probably in the majority of instances, when a new hospital is to be built, a well meaning contributor or local committee sets out to collect "ideas" from hospitals held up as models, giving only secondary thought, if any, to the question whether these hospitals are adapted to the same local needs.

A second consideration emerges from the examination of the figures above referred to. The total hospital bed capacity of the country has increased enormously, yet relatively much less than the number of institutions. The average number of beds to an institution in 1867 was 13; today it is a little over 98. The absolute size of the large hospitals, such as Mount Sinai, New York, for example, in 1868 could "accommodate about 500 patients comfortably"; its present capacity is 500. Pennsylvania Hos-

pital in 1867 had 155 patients; it now can take care of 315. Since the increase in the total number of institutions has been great relatively to the increase in total bed capacity, and since the increase in the bed capacity of the large institutions has been absolutely great, therefore, it follows that the increase in number of small institutions must be enormous, and that the vast majority of hospitals in the country must be well under one hundred beds capacity. Furthermore, the idea of making a survey of the community before building a hospital, has found lodgment, if anywhere, in urban centers, and application to the foundation of large hospitals. A large institution can afford to employ a hospital expert, or a corps of experts, to make preliminary surveys before the plans are drawn. This is obviously out of the question for rural communities and small hospitals. . . .

The moral seems to be twofold: In the first place, there is still need for missionary work in spreading the hospital idea, but this missionary work needs to be directed now, not so much to convincing people of the value of hospitals as to teaching them the necessity of measuring the needs of the community before building or even planning a hospital. In the second place, since small hospitals so greatly outnumber the large institutions, and since cross-roads communities will never be able to command the service of high priced hospital experts, the crying need of the hospital situation today seems to be for an investigation of the hospital needs of various rural communities, with a view to discovering some general principles which may be applied in any specific instance. In no other way, apparently, shall we solve one of the most important, if not the most important, hospital problem of the day.

CONGRESS AND INFLUENZA

BILLS have been introduced into Congress by Senator Harding and Representative Fess of Ohio, for an appropriation of one and a half million dollars for the fight on influenza. These bills make concrete the recommendations of the section on preventive medicine of the American Medical Association.

There should be no delay in the passage of these bills. Effective measures are needed now to prepare against the possible recurrence of influenza. The bills should have been introduced and passed many weeks ago without any special recommendations. Common business sense should have dictated action. Failure to act is indicative of a form of disease which might be diagnosed by a layman as "political hookworm."
